Topos Theory

Lectures 23-24: The unifying methodologies

Olivia Caramello

Toposes as unifying spaces in Mathematics

In this lecture, whenever I use the word ‘topos’, I really mean ‘Grothendieck topos’.

Recall that a **Grothendieck topos** can be seen as:

- a **generalized space**
- a **mathematical universe**
- a **geometric theory modulo ‘Morita-equivalence’** where ‘Morita-equivalence’ is the equivalence relation which identifies two (geometric) theories precisely when they have equivalent categories of models in any Grothendieck topos \mathcal{E} , naturally in \mathcal{E} .

In these lectures, we present a new view of toposes as **unifying spaces** which can serve as **bridges** for transferring information, ideas and results between distinct mathematical theories. This approach, first introduced in my Ph.D. thesis, has already generated ramifications into distinct mathematical fields and points towards a realization of Topos Theory as a **unifying theory of Mathematics**.

- **Model Theory** (a topos-theoretic interpretation of Fraïssé's construction in Model Theory)
- **Algebra** (an application of De Morgan's law to the theory of fields - jointly with P. T. Johnstone)
- **Topology** (a unified approach to Stone-type dualities)
- **Proof Theory** (an equivalence between the traditional proof system of geometric logic and a categorical system based on the notion of Grothendieck topology)
- **Definability** (applications of universal models to definability)

These are just a few examples selected from my research; as I see it, the interest of them especially lies in the fact that they demonstrate the technical usefulness and centrality of the philosophy '*Toposes as bridges*' described below: without much effort, **one can generate an infinite number of new theorems by applying these methodologies!**

Definition

- By a **site of definition** of a Grothendieck topos \mathcal{E} , we mean a site $(\mathcal{C}, \mathcal{J})$ such that $\mathcal{E} \simeq \mathbf{Sh}(\mathcal{C}, \mathcal{J})$.
- We shall say that two geometric theories are **Morita-equivalent** if they have equivalent categories of models in every Grothendieck topos \mathcal{E} , naturally in \mathcal{E} .

Note that ‘to be Morita-equivalent to each other’ defines an **equivalence relation** of the collection of all geometric theories.

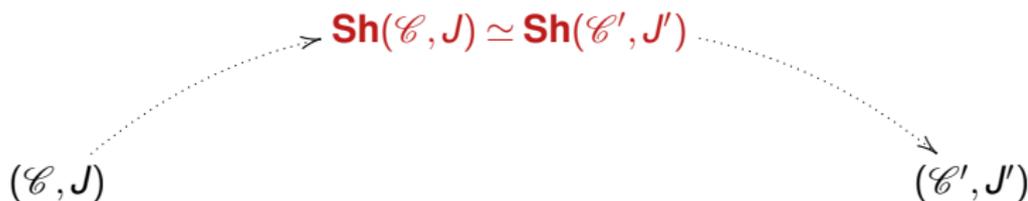

- Two geometric theories are Morita-equivalent if and only if they are biinterpretable in each other (in a generalized sense).
- On the other hand, the notion of Morita-equivalence is a ‘semantical’ one, and we can expect most of the categorical equivalences between categories of models of geometric theories in **Set** to ‘lift’ to Morita-equivalences.

- In fact, many important **dualities** and **equivalences** in Mathematics can be naturally interpreted in terms of **Morita-equivalences** (either as Morita-equivalences themselves or as arising from the process of 'functorializing' Morita-equivalences).
- On the other hand, **Topos Theory** itself is a primary source of Morita-equivalences. Indeed, different representations of the same topos can be interpreted as Morita-equivalences between different mathematical theories.
- It is fair to say that the notion of Morita-equivalence formalizes in many situations the feeling of 'looking at the **same** thing in **different** ways, which explains why it is **ubiquitous** in Mathematics.
- Also, the notion captures the intrinsic dynamism inherent to the notion of mathematical theory; indeed, a mathematical theory **alone** gives rise to an **infinite number** of Morita-equivalences.

- Two geometric theories have equivalent classifying toposes if and only if they are Morita-equivalent to each other.
- Hence, a topos can be seen as a *canonical representative* of equivalence classes of geometric theories modulo Morita-equivalence. So, we can think of a topos as embodying the 'common features' of mathematical theories which are Morita-equivalent to each other.
- The essential features of Morita-equivalences are all 'hidden' inside Grothendieck toposes, and can be revealed by using their different sites of definition.
 - *Conceptually*, a property of geometric theories which is stable under Morita-equivalence *is* a property of their classifying topos.
 - *Technically*, considered the richness and flexibility of topos-theoretic methods, we can expect these properties to be expressible as **topos-theoretic invariants** (in the sense of properties of toposes written in the language of Topos Theory).

- The underlying intuition behind this is that a given mathematical property can manifest itself in several different forms in the context of mathematical theories which have a common 'semantical core' but a different linguistic presentation.
- The remarkable fact is that if the property is formulated as a topos-theoretic invariant on some topos then the expression of it in terms of the different theories classified by the topos is determined to a great extent by the **structural relationship** between the topos and the different sites of definition for it.
- Indeed, the fact that different mathematical theories have equivalent classifying toposes translates into the existence of **different sites** of definition for **one topos**.
- Topos-theoretic invariants can then be used to **transfer** properties from one theory to another.
- In fact, any invariant behaves like a **'pair of glasses'** which allows us to discern certain information which is 'hidden' in the given Morita-equivalence. Different invariants enable us to extract different information.

- This methodology is **technically feasible** because the relationship between a site $(\mathcal{C}, \mathcal{J})$ and the topos $\mathbf{Sh}(\mathcal{C}, \mathcal{J})$ which it 'generates' is often **very natural**, enabling us to easily transfer invariants across different sites.
- A topos thus acts as a '**bridge**' which allows the transfer of information and results between theories which are Morita-equivalent to each other:

- The **level of generality** represented by topos-theoretic invariants is ideal to capture several important features of mathematical theories. Indeed, as shown in my thesis, important topos-theoretic invariants considered on the classifying topos $\mathbf{Set}[\mathbb{T}]$ of a geometric theory \mathbb{T} translate into interesting logical (i.e. syntactic or semantic) properties of \mathbb{T} .
- The fact that topos-theoretic invariants often specialize to important properties or constructions of natural mathematical interest is a clear indication of the **centrality** of these concepts in Mathematics. In fact, whatever happens at the level of toposes has '**uniform**' ramifications in Mathematics as a whole.

- The '**working mathematician**' could very well attempt to formulate his or her properties of interest in terms of topos-theoretic invariants, and derive equivalent versions of them by using alternative sites.
- Also, whenever one discovers a duality or an equivalence of mathematical theories, one should try to interpret it in terms of a Morita-equivalence, calculate the classifying topos of the two theories and apply topos-theoretic methods to extract new information about it.
- These methodologies define a new way of doing Mathematics which is '**upside-down**' compared with the 'usual' one. Instead of starting with simple ingredients and combining them to build more complicated structures, one assumes as primitive ingredients rich and sophisticated mathematical entities, namely **Morita-equivalences** and **topos-theoretic invariants**, and extracts from them a huge amount of information relevant for classical mathematics.

- There is an strong element of **automatism** in these techniques; by means of them, one can generate **new mathematical results** without really making any creative effort: indeed, in many cases one can just readily apply the general characterizations connecting properties of sites and topos-theoretic invariants to the particular Morita-equivalence under consideration.
- The results generated in this way are in general **non-trivial**; in some cases they can be rather 'weird' according to the usual mathematical standards (although they might still be quite deep) but, with a careful choice of Morita-equivalences and invariants, one can easily get interesting and natural mathematical results.
- In fact, a **lot of information** that is not visible with the usual 'glasses' is revealed by the application of this machinery.
- On the other hand, the range of applicability of these methods is boundless within Mathematics, by the very **generality** of the notion of topos.

Definition

By a **topos-theoretic invariant** we mean a property of (or a construction involving) toposes which is stable under categorical equivalence.

Examples of topos-theoretic invariants include:

- to be a **classifying topos** for a geometric theory.
- to be a **Boolean** (resp. **De Morgan**) topos.
- to be an **atomic** topos.
- to be **equivalent to a presheaf topos**.
- to be a **connected** (resp. **locally connected**, **compact**) topos.
- to be a **subtopos** (in the sense of geometric inclusion) of a given topos.
- to have **enough points**.
- to be **two-valued**.

Of course, there are a great many others, and one can always introduce new ones!

Sometimes, in order to obtain more specific results, it is convenient to consider **invariants of objects** of toposes rather than 'global' invariants of toposes.

Definition

- A geometric theory \mathbb{T} over a signature Σ is said to be of **presheaf type** if it is classified by a presheaf type.
- A model M of a theory of presheaf type \mathbb{T} in the category **Set** is said to be **finitely presentable** if the functor $\text{Hom}_{\mathbb{T}\text{-mod}(\mathbf{Set})}(M, -) : \mathbb{T}\text{-mod}(\mathbf{Set}) \rightarrow \mathbf{Set}$ preserves filtered colimits.

The class of theories of presheaf type contains all the finitary algebraic theories and many other significant mathematical theories.

Fact

For any theory of presheaf type \mathcal{C} , we have two different representations of its classifying topos:

$$[f.p.\mathbb{T}\text{-mod}(\mathbf{Set}), \mathbf{Set}] \simeq \mathbf{Sh}(\mathcal{C}_{\mathbb{T}}, \mathcal{J}_{\mathbb{T}})$$

where $f.p.\mathbb{T}\text{-mod}(\mathbf{Set})$ is the category of finitely presentable \mathbb{T} -models.

Note that this gives us a perfect opportunity to test the effectiveness of the philosophy 'toposes as bridges'!

Theorem

Let \mathbb{T} be a theory of presheaf type such that the category $f.p.\mathbb{T}\text{-mod}(\mathbf{Set})$ satisfies both amalgamation and joint embedding properties. Then any two countable homogeneous \mathbb{T} -models in \mathbf{Set} are isomorphic.

The quotient of \mathbb{T} axiomatizing the homogeneous \mathbb{T} -models is precisely the **Booleanization** of \mathbb{T} .

The theorem is proved by means of an investigation of topos **$\mathbf{Sh}(f.p.\mathbb{T}\text{-mod}(\mathbf{Set})^{\text{op}}, J_{at})$**

- geometrically
- syntactically
- semantically

The main result arises from an **integration** of these three lines of investigation according to the principles 'toposes as bridges' explained above.
