Universidad Nacional de Colombia, 26-30 October 2020
The “unifying notion” of topos

“It is the topos theme which is this “bed” or “deep river” where come to be married geometry and algebra, topology and arithmetic, mathematical logic and category theory, the world of the “continuous” and that of “discontinuous” or discrete structures. It is what I have conceived of most broad to perceive with finesse, by the same language rich of geometric resonances, an “essence” which is common to situations most distant from each other coming from one region or another of the vast universe of mathematical things”.

A. Grothendieck

Topos theory can be regarded as a unifying subject in Mathematics, with great relevance as a framework for systematically investigating the relationships between different mathematical theories and studying them by means of a multiplicity of different points of view. Its methods are transversal to the various fields and complementary to their own specialized techniques. In spite of their generality, the topos-theoretic techniques are liable to generate insights which would be hardly attainable otherwise and to establish deep connections that allow effective transfers of knowledge between different contexts.

Toposes as unifying ‘bridges’

The unifying nature of toposes is intimately tied to the fact that Grothendieck toposes are objects that can be built from a great variety of different mathematical situations, ideally in such a way that essential features of such situations can be captured by means of topos-theoretic invariants on the associated toposes.

Indeed, the possibility of presenting a given topos is multiple ways is at the heart of the bridge technique, introduced in 2010 in the paper “The unification of Mathematics via Topos Theory” as a means to effectively use toposes as unifying spaces across different mathematical contexts, as well as for studying mathematical theories in an intrinsically dynamical way.

The key idea is that the possibility of presenting a topos in a multitude of different ways can be effectively exploited for building unifying ‘bridges’ between theories having an equivalent, or strictly related, mathematical content.

These ‘bridges’ allow effective and often deep transfers of notions, ideas and results across the theories.

In fact, ‘bridges’ have proved useful not only for connecting different theories with each other, but also for working inside a given mathematical theory and investigating it from a multiplicity of different points of view.
The most classical way for building toposes is through sites (indeed, a Grothendieck topos is, by definition, any category equivalent to the category of sheaves on a small-generated sites).

Still, toposes can also be canonically associated with groups (or more generally topological or localic groupoids) or with (first-order geometric) theories or with non-commutative structures such as quantales or quantaloids, etc.

In this course we shall study morphisms and equivalences of toposes from the (geometric) point of view of their site presentations.
The notion of **topos** was introduced in the early sixties by A. Grothendieck with the aim of bringing a topological or geometric intuition also in areas where actual topological spaces do not occur.

Grothendieck realized that many important properties of topological spaces $X$ can be naturally formulated as (invariant) properties of the categories $\text{Sh}(X)$ of sheaves of sets on the spaces.

He then defined **toposes** as more general categories of sheaves of sets, by replacing the topological space $X$ by a (small) site, that is a pair $(\mathcal{C}, J)$ consisting of a (small) category $\mathcal{C}$ and a ‘generalized notion of covering’ $J$ on it, and taking sheaves (in a generalized sense) over the site:

$$
\begin{align*}
X & \rightarrow \text{Sh}(X) \\
(\mathcal{C}, J) & \rightarrow \text{Sh}(\mathcal{C}, J)
\end{align*}
$$
Sieves

The notion of Grothendieck topology on a category represents a ‘categorification’ of the classical notion of covering of an open set of a topological space by a family of open subsets. In order to define it in full generality, one needs to talk about sieves.

Definition

• Given a category $\mathcal{C}$ and an object $c \in \text{Ob}(\mathcal{C})$, a presieve $P$ in $\mathcal{C}$ on $c$ is a collection of arrows in $\mathcal{C}$ with codomain $c$.
• Given a category $\mathcal{C}$ and an object $c \in \text{Ob}(\mathcal{C})$, a sieve $S$ in $\mathcal{C}$ on $c$ is a collection of arrows in $\mathcal{C}$ with codomain $c$ such that

$$f \in S \Rightarrow f \circ g \in S$$

whenever this composition makes sense.
• We say that a sieve $S$ is generated by a presieve $P$ on an object $c$ if it is the smallest sieve containing it, that is if it is the collection of arrows to $c$ which factor through an arrow in $P$.

If $S$ is a sieve on $c$ and $h : d \rightarrow c$ is any arrow to $c$, then

$$h^*(S) := \{g \mid \text{cod}(g) = d, \ h \circ g \in S\}$$

is a sieve on $d$. 
**Grothendieck topologies**

**Definition**

- **A Grothendieck topology** on a category $\mathcal{C}$ is a function $J$ which assigns to each object $c$ of $\mathcal{C}$ a collection $J(c)$ of sieves on $c$ in such a way that
  
  (i) **(maximality axiom)** the maximal sieve $M_c = \{ f | \text{cod}(f) = c \}$ is in $J(c)$;
  
  (ii) **(stability axiom)** if $S \in J(c)$, then $f^*(S) \in J(d)$ for any arrow $f : d \to c$;
  
  (iii) **(transitivity axiom)** if $S \in J(c)$ and $R$ is any sieve on $c$ such that $f^*(R) \in J(d)$ for all $f : d \to c$ in $S$, then $R \in J(c)$.

The sieves $S$ which belong to $J(c)$ for some object $c$ of $\mathcal{C}$ are said to be $J$-covering.

- **A site** (resp. small site) is a pair $(\mathcal{C}, J)$ where $\mathcal{C}$ is a category (resp. a small category) and $J$ is a Grothendieck topology on $\mathcal{C}$.

- A site $(\mathcal{C}, J)$ is said to be **small-generated** if $\mathcal{C}$ is locally small and has a small $J$-dense subcategory (that is, a category $\mathcal{D}$ such that every object of $\mathcal{C}$ admits a $J$-covering sieve generated by arrows whose domains lie in $\mathcal{D}$, and for every arrow $f : d \to c$ in $\mathcal{C}$ where $d$ lies in $\mathcal{D}$ the family of arrows $g : \text{dom}(g) \to d$ such that $f \circ g$ lies in $\mathcal{D}$ generates a $J$-covering sieve).
Examples of Grothendieck topologies

• For any (small) category $\mathcal{C}$, the trivial topology on $\mathcal{C}$ is the Grothendieck topology in which the only sieve covering an object $c$ is the maximal sieve $M_c$.

• The dense topology $D$ on a category $\mathcal{C}$ is defined by: for a sieve $S$,

$$S \in D(c) \quad \text{if and only if} \quad \text{for any } f : d \to c \text{ there exists } g : e \to d \text{ such that } f \circ g \in S.$$ 

If $\mathcal{C}$ satisfies the right Ore condition i.e. the property that any two arrows $f : d \to c$ and $g : e \to c$ with a common codomain $c$ can be completed to a commutative square

\[ \bullet \rightarrow d \\
\downarrow \\
\downarrow \\
\downarrow \\
e \rightarrow c \]

then the dense topology on $\mathcal{C}$ specializes to the atomic topology on $\mathcal{C}$ i.e. the topology $J_\text{at}$ defined by: for a sieve $S$,

$$S \in J_\text{at}(c) \quad \text{if and only if} \quad S \neq \emptyset.$$
Examples of Grothendieck topologies

• If $X$ is a topological space, the usual notion of covering in Topology gives rise to the following Grothendieck topology $J_{\mathcal{O}(X)}$ on the poset category $\mathcal{O}(X)$: for a sieve $S = \{U_i \hookrightarrow U \mid i \in I\}$ on $U \in Ob(\mathcal{O}(X))$,

$$S \in J_{\mathcal{O}(X)}(U) \text{ if and only if } \bigcup_{i \in I} U_i = U.$$

• More generally, given a frame (or complete Heyting algebra) $H$, we can define a Grothendieck topology $J_H$, called the canonical topology on $H$, by:

$$\{a_i \mid i \in I\} \in J_H(a) \text{ if and only if } \bigvee_{i \in I} a_i = a.$$

• The Zariski topology on the opposite of the category $\text{Rng}_{\text{f.g.}}$ of finitely generated commutative rings with unit is defined by: for any cosieve $S$ in $\text{Rng}_{\text{f.g.}}$ on an object $A$, $S \in Z(A)$ if and only if $S$ contains a finite family $\{\xi_i : A \rightarrow A_{f_i} \mid 1 \leq i \leq n\}$ of canonical maps $\xi_i : A \rightarrow A_{f_i}$ in $\text{Rng}_{\text{f.g.}}$, where $\{f_1, \ldots, f_n\}$ is a set of elements of $A$ which is not contained in any proper ideal of $A$.

• Given a (first-order geometric) theory $\mathcal{T}$, one can naturally associate a site $(\mathcal{C}_\mathcal{T}, J_\mathcal{T})$ with it, called its syntactic site, which embodies essential aspects of the syntax and proof theory of $\mathcal{T}$. 
Sheaves on a site

Definition

• A presheaf on a (small) category \( C \) is a functor \( P : C^{\text{op}} \to \text{Set} \).

• Let \( P : C^{\text{op}} \to \text{Set} \) be a presheaf on \( C \) and \( S \) be a sieve on an object \( c \) of \( C \).

A matching family for \( S \) of elements of \( P \) is a function which assigns to each arrow \( f : d \to c \) in \( S \) an element \( x_f \in P(d) \) in such a way that

\[
P(g)(x_f) = x_{f \circ g} \quad \text{for all } g : e \to d.
\]

An amalgamation for such a family is a single element \( x \in P(c) \) such that

\[
P(f)(x) = x_f \quad \text{for all } f \text{ in } S.
\]
Sheaves on a site

- Given a site \((\mathcal{C}, J)\), a presheaf on \(\mathcal{C}\) is a \textit{J-sheaf} if every matching family for any \(J\)-covering sieve on any object of \(\mathcal{C}\) has a unique amalgamation.

- The category \(\text{Sh}(\mathcal{C}, J)\) of \textit{sheaves on the site} \((\mathcal{C}, J)\) is the full subcategory of \([\mathcal{C}^{\text{op}}, \text{Set}]\) on the presheaves which are \(J\)-sheaves.

- A \textit{Grothendieck topos} is any category equivalent to the category of sheaves on a small (or equivalently, small-generated) site.
Examples of toposes

The following basic examples show that toposes can be naturally attached to mathematical notions as different as (small) categories, topological spaces, or groups.

Examples

• For any (small) category $\mathcal{C}$, $[\mathcal{C}^{\text{op}}, \text{Set}]$ is the category of sheaves $\mathbf{Sh}(\mathcal{C}, T)$ where $T$ is the trivial topology on $\mathcal{C}$.

• For any topological space $X$, $\mathbf{Sh}(\mathcal{O}(X), J_{\mathcal{O}(X)})$ is equivalent to the usual category $\mathbf{Sh}(X)$ of sheaves on $X$.

• For any (topological) group $G$, the category $BG = \text{Cont}(G)$ of continuous actions of $G$ on discrete sets is a Grothendieck topos (equivalent, as we shall see, to the category $\mathbf{Sh}(\text{Cont}_{t}(G), J_{\text{at}})$ of sheaves on the full subcategory $\text{Cont}_{t}(G)$ on the non-empty transitive actions with respect to the atomic topology).
Basic properties of Grothendieck toposes

Grothendieck toposes satisfy all the categorical properties that one might hope for:

**Theorem**

Let \((\mathcal{C}, J)\) be a site. Then

- the inclusion \(\text{Sh}(\mathcal{C}, J) \hookrightarrow [\mathcal{C}^{\text{op}}, \text{Set}]\) has a left adjoint \(a : [\mathcal{C}^{\text{op}}, \text{Set}] \rightarrow \text{Sh}(\mathcal{C}, J)\) (called the associated sheaf functor), which preserves finite limits.
- The category \(\text{Sh}(\mathcal{C}, J)\) has all (small) limits, which are preserved by the inclusion functor \(\text{Sh}(\mathcal{C}, J) \hookrightarrow [\mathcal{C}^{\text{op}}, \text{Set}]\); in particular, limits are computed pointwise and the terminal object \(1_{\text{Sh}(\mathcal{C}, J)}\) of \(\text{Sh}(\mathcal{C}, J)\) is the functor \(T : \mathcal{C}^{\text{op}} \rightarrow \text{Set}\) sending each object \(c \in \text{Ob}(\mathcal{C})\) to the singleton \(\{\ast\}\).
- The associated sheaf functor \(a : [\mathcal{C}^{\text{op}}, \text{Set}] \rightarrow \text{Sh}(\mathcal{C}, J)\) preserves colimits; in particular, \(\text{Sh}(\mathcal{C}, J)\) has all (small) colimits.
- The category \(\text{Sh}(\mathcal{C}, J)\) has **exponentials**, which are constructed as in the topos \([\mathcal{C}^{\text{op}}, \text{Set}]\).
- The category \(\text{Sh}(\mathcal{C}, J)\) has a **subobject classifier**.
- The category \(\text{Sh}(\mathcal{C}, J)\) has a **separating set of objects**.
Geometric morphisms

The natural, topologically motivated, notion of morphism of Grothendieck toposes is that of geometric morphism. The natural notion of morphism of geometric morphisms if that of geometric transformation.

Definition

(i) Let $\mathcal{E}$ and $\mathcal{F}$ be toposes. A geometric morphism $f : \mathcal{E} \to \mathcal{F}$ consists of a pair of functors $f_* : \mathcal{E} \to \mathcal{F}$ (the direct image of $f$) and $f^* : \mathcal{F} \to \mathcal{E}$ (the inverse image of $f$) together with an adjunction $f^* \dashv f_*$, such that $f^*$ preserves finite limits.

(ii) Let $f$ and $g : \mathcal{E} \to \mathcal{F}$ be geometric morphisms. A geometric transformation $\alpha : f \to g$ is defined to be a natural transformation $\alpha : f^* \to g^*$.

(iii) A point of a topos $\mathcal{E}$ is a geometric morphism $\textbf{Set} \to \mathcal{E}$.

- Grothendieck toposes and geometric morphisms between them form a 2-category.
- Given two toposes $\mathcal{E}$ and $\mathcal{F}$, geometric morphisms from $\mathcal{E}$ to $\mathcal{F}$ and geometric transformations between them form a category, denoted by $\textbf{Geom}(\mathcal{E}, \mathcal{F})$. 
Examples of geometric morphisms

- A continuous function $f : X \to Y$ between topological spaces gives rise to a geometric morphism $\text{Sh}(f) : \text{Sh}(X) \to \text{Sh}(Y)$. The direct image $\text{Sh}(f)_*$ sends a sheaf $F \in \text{Ob}(\text{Sh}(X))$ to the sheaf $\text{Sh}(f)_*(F)$ defined by $\text{Sh}(f)_*(F)(V) = F(f^{-1}(V))$ for any open subset $V$ of $Y$. The inverse image $\text{Sh}(f)^*$ acts on étale bundles over $Y$ by sending an étale bundle $p : E \to Y$ to the étale bundle over $X$ obtained by pulling back $p$ along $f : X \to Y$.

- Every Grothendieck topos $\mathcal{E}$ has a unique geometric morphism $\mathcal{E} \to \text{Set}$. The direct image is the global sections functor $\Gamma : \mathcal{E} \to \text{Set}$, sending an object $e \in \mathcal{E}$ to the set $\text{Hom}_{\mathcal{E}}(1_{\mathcal{E}}, e)$, while the inverse image functor $\Delta : \text{Set} \to \mathcal{E}$ sends a set $S$ to the coproduct $\bigsqcup_{s \in S} 1_{\mathcal{E}}$.

- For any site $(\mathcal{C}, J)$, the pair of functors formed by the inclusion $\text{Sh}(\mathcal{C}, J) \hookrightarrow [\mathcal{C}^{\text{op}}, \text{Set}]$ and the associated sheaf functor $a : [\mathcal{C}^{\text{op}}, \text{Set}] \to \text{Sh}(\mathcal{C}, J)$ yields a geometric morphism $i : \text{Sh}(\mathcal{C}, J) \to [\mathcal{C}^{\text{op}}, \text{Set}]$.

- For any Grothendieck topos $\mathcal{E}$ and any morphism $f : P \to Q$ in $\mathcal{E}$, the pullback functor $f^* : \mathcal{E}/Q \to \mathcal{E}/P$ has both a left adjoint (namely, the functor $\Sigma_f$ given by composition with $f$) and a right adjoint $\pi_f$. It is therefore the inverse image of a geometric morphism $\mathcal{E}/P \to \mathcal{E}/Q$. 
Theorem

Let $\mathcal{C}$ be a small category, $\mathcal{E}$ be a locally small cocomplete category and $A : \mathcal{C} \to \mathcal{E}$ a functor. Then we have an adjunction

$$L_A : [\mathcal{C}^{\text{op}}, \textbf{Set}] \rightleftarrows \mathcal{E} : R_A$$

where the right adjoint $R_A : \mathcal{E} \to [\mathcal{C}^{\text{op}}, \textbf{Set}]$ is defined for each $e \in \text{Ob}(\mathcal{E})$ and $c \in \text{Ob}(\mathcal{C})$ by:

$$R_A(e)(c) = \text{Hom}_\mathcal{E}(A(c), e)$$

and the left adjoint $L_A : [\mathcal{C}^{\text{op}}, \textbf{Set}] \to \mathcal{E}$ is defined by

$$L_A(P) = \text{colim}(A \circ \pi_P),$$

where $\pi_P$ is the canonical projection functor $\int P \to \mathcal{C}$ from the category of elements $\int P$ of $P$ to $\mathcal{C}$. 
The functor $L_A$ can be considered as a generalized tensor product, since, by the construction of colimits in terms of coproducts and coequalizers, we have the following coequalizer diagram:

$$\coprod_{c \in C, p \in P(c)} A(c') \xrightarrow{\theta} \prod_{c' \in C, p \in P(c)} \xrightarrow{\tau} \prod_{c \in C, p \in P(c)} A(c) \xrightarrow{\phi} L_A(P),$$

where

$$\theta(c, p, u, x) = (c', P(u)(p), x)$$

and

$$\tau(c, p, u, x) = (c, p, A(u)(x)).$$

For this reason, we shall also denote $L_A$ by

$$- \otimes_C A : [C^{\text{op}}, \text{Set}] \rightarrow \mathcal{E}.$$

We can rewrite the above coequalizer as follows:

$$\coprod_{c, c' \in C} P(c) \times \text{Hom}_C(c', c) \times A(c') \xrightarrow{\theta} \prod_{c \in C} P(c) \times A(c) \xrightarrow{\phi} P \otimes_C A.$$

From this we see that this definition is symmetric in $P$ and $A$, that is

$$P \otimes_C A \cong A \otimes_{C^{\text{op}}} P.$$
A couple of corollaries

Corollary
Every presheaf is a colimit of representables. More precisely, for any presheaf \( P : C^{\text{op}} \to \text{Set} \), we have

\[
P \cong \operatorname{colim}(y_C \circ \pi_P),
\]

where \( y_C : C \to [C^{\text{op}}, \text{Set}] \) is a Yoneda embedding and \( \pi_P \) is the canonical projection \( \int P \to C \).

Corollary
For any small category \( C \), the topos \( [C^{\text{op}}, \text{Set}] \) is the free cocompletion of \( C \) (via the Yoneda embedding \( y_C \)); that is, any functor \( A : C \to \mathcal{E} \) to a cocomplete category \( \mathcal{E} \) extends, uniquely up to isomorphism, to a colimit-preserving functor \( [C^{\text{op}}, \text{Set}] \to \mathcal{E} \) along \( y_C : C \to [C^{\text{op}}, \text{Set}] \).
Separating sets of objects

Definition

A separating set of objects for a Grothendieck topos $\mathcal{E}$ is a set $C$ of objects of $\mathcal{E}$ such that for any object $A$ of $\mathcal{E}$, the collection of arrows from objects in $C$ to $A$ is epimorphic.

Proposition

For any site $(C, J)$, the collection of objects of the form $l_J(c)$ (for $c \in C$), where

$$l_J : C \to \text{Sh}(C, J)$$

is the composite of the Yoneda embedding $y_C : C \to [C^{\text{op}}, \text{Set}]$ with the associated sheaf functor $a_J : [C^{\text{op}}, \text{Set}] \to \text{Sh}(C, J)$, is a separating set of objects for the topos $\text{Sh}(C, J)$.

The following theorem provides a sort of converse to this proposition:

Theorem

For any set of objects $C$ of $\mathcal{E}$ which is separating, we have an equivalence

$$\mathcal{E} \simeq \text{Sh}(C, J^\text{can}_\mathcal{E}|_C)$$

where $J^\text{can}_\mathcal{E}|_C$ is the Grothendieck topology induced on $C$ (regarded as a full subcategory of $\mathcal{E}$).
Geometric morphisms as flat functors I

Definition

• A functor $A : C \to \mathcal{E}$ from a small category $C$ to a locally small topos $\mathcal{E}$ with small colimits is said to be flat if the functor $- \otimes_C A : [C^{\text{op}}, \text{Set}] \to \mathcal{E}$ preserves finite limits.
• The full subcategory of $[C, \mathcal{E}]$ on the flat functors will be denoted by $\text{Flat}(C, \mathcal{E})$.

Theorem

Let $C$ be a small category and $\mathcal{E}$ be a Grothendieck topos. Then we have an equivalence of categories

$$\text{Geom}(\mathcal{E}, [C^{\text{op}}, \text{Set}]) \simeq \text{Flat}(C, \mathcal{E})$$

(natural in $\mathcal{E}$), which sends

• a flat functor $A : C \to \mathcal{E}$ to the geometric morphism $\mathcal{E} \to [C^{\text{op}}, \text{Set}]$ determined by the functors $R_A$ and $- \otimes_C A$, and
• a geometric morphism $f : \mathcal{E} \to [C^{\text{op}}, \text{Set}]$ to the flat functor given by the composite $f^* \circ y_C$ of $f^* : [C^{\text{op}}, \text{Set}] \to \mathcal{E}$ with the Yoneda embedding $y_C : C \to [C^{\text{op}}, \text{Set}]$.

Flat = filtering

Definition

A functor $F : \mathcal{C} \to \mathcal{E}$ from a small category $\mathcal{C}$ to a Grothendieck topos $\mathcal{E}$ is said to be **filtering** if it satisfies the following conditions:

(a) For any object $E$ of $\mathcal{E}$ there exist an epimorphic family

\[ \{ e_i : E_i \to E \mid i \in I \} \]

in $\mathcal{E}$ and for each $i \in I$ an object $b_i$ of $\mathcal{C}$ and a generalized element $E_i \to F(b_i)$ in $\mathcal{E}$.

(b) For any two objects $c$ and $d$ in $\mathcal{C}$ and any generalized element $\langle x, y \rangle : E \to F(c) \times F(d)$ in $\mathcal{E}$ there is an epimorphic family

\[ \{ e_i : E_i \to E \mid i \in I \} \]

in $\mathcal{E}$ and for each $i \in I$ an object $b_i$ of $\mathcal{C}$ with arrows $u_i : b_i \to c$ and $v_i : b_i \to d$ in $\mathcal{C}$ and a generalized element $z_i : E_i \to F(b_i)$ in $\mathcal{E}$ such that $\langle F(u_i), F(v_i) \rangle \circ z_i = \langle x, y \rangle \circ e_i$ for all $i \in I$.

(c) For any two parallel arrows $u, v : d \to c$ in $\mathcal{C}$ and any generalized element $x : E \to F(d)$ in $\mathcal{E}$ for which $F(u) \circ x = F(v) \circ x$, there is an epimorphic family

\[ \{ e_i : E_i \to E \mid i \in I \} \]

in $\mathcal{E}$ and for each $i \in I$ an arrow $w_i : b_i \to d$ and a generalized element $y_i : E_i \to F(b_i)$ such that $u \circ w_i = v \circ w_i$ and $F(w_i) \circ y_i = x \circ e_i$ for all $i \in I$.

Theorem (Mac Lane and Moerdijk)

A functor $F : \mathcal{C} \to \mathcal{E}$ from a small category $\mathcal{C}$ to a Grothendieck topos $\mathcal{E}$ is **flat** if and only if it is **filtering**.

Remarks

- For any small category $\mathcal{C}$, a functor $P : \mathcal{C} \to \text{Set}$ is filtering if and only if its category of elements $\int P$ is a filtered category (equivalently, if it is a filtered colimit of representables).
- For any small cartesian category $\mathcal{C}$, a functor $\mathcal{C} \to \mathcal{E}$ is flat if and only if it preserves finite limits.
Geometric morphisms to $\text{Sh}(\mathcal{C}, J)$

**Definition**
If $(\mathcal{C}, J)$ is a site, a flat functor $F : \mathcal{C} \to \mathcal{E}$ to a Grothendieck topos is said to be $J$-continuous if it sends $J$-covering sieves to epimorphic families.

The full subcategory of $\text{Flat}(\mathcal{C}, \mathcal{E})$ on the $J$-continuous flat functors will be denoted by $\text{Flat}_J(\mathcal{C}, \mathcal{E})$.

**Theorem**
*For any site $(\mathcal{C}, J)$ and Grothendieck topos $\mathcal{E}$, the above-mentioned equivalence between geometric morphisms and flat functors restricts to an equivalence of categories

$$\text{Geom}(\mathcal{E}, \text{Sh}(\mathcal{C}, J)) \simeq \text{Flat}_J(\mathcal{C}, \mathcal{E})$$

natural in $\mathcal{E}$.

**Sketch of proof.**
Appeal to the previous theorem

- identifying the geometric morphisms $\mathcal{E} \to \text{Sh}(\mathcal{C}, J)$ with the geometric morphisms $\mathcal{E} \to [\mathcal{C}^{\text{op}}, \text{Set}]$ which factor through the canonical geometric inclusion $\text{Sh}(\mathcal{C}, J) \hookrightarrow [\mathcal{C}^{\text{op}}, \text{Set}]$, and
- using the characterization of such morphisms as the geometric morphisms $f : \mathcal{E} \to [\mathcal{C}^{\text{op}}, \text{Set}]$ such that the composite $f^* \circ y$ of the inverse image functor $f^*$ of $f$ with the Yoneda embedding $y : \mathcal{C} \to [\mathcal{C}^{\text{op}}, \text{Set}]$ sends $J$-covering sieves to epimorphic families in $\mathcal{E}$.  

Morphisms and comorphisms of sites

Geometric morphisms can be naturally induced by functors between sites satisfying appropriate properties:

Definition

• A morphism of sites $(C, J) \rightarrow (D, K)$ is a functor $F : C \rightarrow D$ such that the composite $l' \circ F$, where $l'$ is the canonical functor $D \rightarrow \text{Sh}(D, K)$, is flat and $J$-continuous. If $C$ and $D$ have finite limits then $F$ is a morphism of sites if and only if it preserves finite limits.

• A comorphism of sites $(D, K) \rightarrow (C, J)$ is a functor $\pi : D \rightarrow C$ which has the covering-lifting property (in the sense that for any $d \in D$ and any $J$-covering sieve $S$ on $\pi(d)$ there is a $K$-covering sieve $R$ on $d$ such that $\pi(R) \subseteq S$).

We have the following well-known fundamental result, which we shall discuss in detail below:

Theorem

• Every morphism of sites $F : (C, J) \rightarrow (D, K)$ induces a geometric morphism $\text{Sh}(F) : \text{Sh}(D, K) \rightarrow \text{Sh}(C, J)$.

• Every comorphism of sites $\pi : (D, K) \rightarrow (C, J)$ induces a geometric morphism $C_{\pi} : \text{Sh}(D, K) \rightarrow \text{Sh}(C, J)$.
We can **explicitly characterize** the functors which are morphisms of sites by using:

- the **characterization of filtering functors** with values in a Grothendieck topos as functors which send certain families to epimorphic families,

- the fact that the image under the associated sheaf functor of a family of natural transformations with common codomain is epimorphic if and only if the family is locally jointly surjective, and

- the following description of the arrows in a Grothendieck topos between objects coming from a site in terms of **locally compatible families of arrows in the site**.
Arrows in a Grothendieck topos

Given a site \((C, J)\), for two arrows \(h, k : c \to d\) in \(C\) we shall write \(h \equiv_J k\) for \(J\)-local equality, that is, to mean that there exists a \(J\)-covering sieve \(S\) on \(c\) such that \(h \circ f = k \circ f\) for every \(f \in S\). Notice that, denoting by \(l\) the canonical functor \(C \to \text{Sh}(C, J)\), \(l(h) = l(k)\) if and only if \(h \equiv_J k\).

**Proposition**

Let \((C, J)\) be a small-generated site.

(i) Then any arrow \(\xi : l(c) \to l(d)\) in \(\text{Sh}(C, J)\) admits a **local representation** by a family of arrows

\[
\{f_u : c_u \to c, g_u : c_u \to d \mid u \in U\}
\]

such that

\[
\{f_u : c_u \to c \mid u \in U\}
\]

generates a \(J\)-covering sieve, for any object \(e\) and arrows \(h : e \to c_u\) and \(k : e \to c_{u'}\) such that \(f_u \circ h = f_{u'} \circ k\) we have \(g_u \circ h \equiv_J g_{u'} \circ k\), and \(\xi \circ l(f_u) = l(g_u)\) for every \(u \in U\).

(ii) Conversely, any family \(\mathcal{F} : \{f_u : c_u \to c, g_u : c_u \to d \mid u \in U\}\) such that \(\{f_u : c_u \to c \mid u \in U\}\) generates a \(J\)-covering sieve and for any object \(e\) and arrows \(h : e \to c_u\) and \(k : e \to c_{u'}\) such that \(f_u \circ h = f_{u'} \circ k\) we have \(g_u \circ h \equiv_J g_{u'} \circ k\), determines a unique arrow \(\xi_{\mathcal{F}} : l(c) \to l(d)\) in \(\text{Sh}(C, J)\) such that

\[
\xi_{\mathcal{F}} \circ l(f_u) = l(g_u)\]

for every \(u \in U\).
(iii) Two families $\mathcal{F} = \{ f_u : c_u \to c, g_u : c_u \to d \mid u \in U \}$ and $\mathcal{F}' = \{ f'_v : e_v \to c, g'_v : e_v \to d \mid v \in V \}$ as in (ii) determine the same arrow $l(c) \to l(d)$ (i.e. $\xi_\mathcal{F} = \xi_\mathcal{F}'$) if and only if they are locally equal on a common refinement, i.e. if there exist a $J$-covering family $\{ a_k : b_k \to c \mid k \in K \}$ and factorizations of it through both of them by arrows $x_k : b_k \to c_{u(k)}$ and $y_k : b_k \to e_{v(k)}$ (i.e. $f_{u(k)} \circ x_k = a_k = f'_{v(k)} \circ y_k$ for every $k \in K$) such that $g_{u(k)} \circ x_k \equiv_J g'_{v(k)} \circ y_k$ for every $k \in K$.

(iv) Given two families $\mathcal{F} = \{ f_u : c_u \to c, g_u : c_u \to d \mid u \in U \}$ and $\mathcal{G} = \{ h_v : d_v \to d, k_v : d_v \to e \mid v \in V \}$, the composite arrow $\xi_\mathcal{G} \circ \xi_\mathcal{F} : l(c) \to l(e)$ is induced as in (ii) by the family $\{ f_u \circ x : \text{dom}(x) \to c, k_v \circ y : \text{dom}(y) \to e \mid (u, v, x, y) \in Z \}$, where $Z = \{(u, v, x, y) \mid u \in U, v \in V, \text{dom}(x) = \text{dom}(y), \text{cod}(x) = c_u, \text{cod}(y) = d_v, h_v \circ y = g_u \circ x \}$. 
Proposition

Let \((\mathcal{C}, J)\) be a small-generated site and \(a_J\) the associated sheaf functor \([\mathcal{C}^{\text{op}}, \text{Set}] \to \text{Sh}(\mathcal{C}, J)\). Then

(i) An arrow \(\xi : l(c) \to a_J(P)\) in \(\text{Sh}(\mathcal{C}, J)\) (equivalently, an element of \(a_J(P)(c)\)) can be identified with an equivalence class of families \(\{x_f \in P(\text{dom}(f)) \mid f \in S\}\) of elements of \(P\) indexed by the arrows \(f\) of a \(J\)-covering sieve \(S\) on \(c\) which are locally matching in the sense that for any arrow \(g\) composable with an arrow \(f \in S\), \(x_f \circ g \equiv_J P(g)(x_f)\), modulo the equivalence which identifies two such families when they are locally equal on a common refinement.

(ii) Any such family yields a local representation of \(\xi\) in the sense that \(\xi \circ l(f) = r_{x_f}\) for each \(f \in S\), where \(r_{x_f}\) is the image under \(a_J\) of the arrow \(y_C(\text{dom}(f)) \to P\) corresponding to the element \(x_f \in P(\text{dom}(f))\) via the Yoneda lemma.

Remark

The proposition gives an explicit description of the associated sheaf functor \(a_J(P)\) of a presheaf \(P\), different from the usual construction of it by means of the double plus construction. This alternative construction of the associated sheaf functor seems to have been first discovered (albeit not published) by Eduardo Dubuc in the eighties.
J-functional relations

More generally, for any presheaves $P, Q \in [\mathcal{C}^{\text{op}}, \textbf{Set}]$, the arrows $a_J(P) \to a_J(Q)$ in $\text{Sh}(\mathcal{C}, J)$ are in natural bijection with the $J$-functional relations from $P$ to $Q$ in $[\mathcal{C}^{\text{op}}, \textbf{Set}]$, in the sense of the following

Definition

In a presheaf topos $[\mathcal{C}^{\text{op}}, \textbf{Set}]$, a relation $R \hookrightarrow P \times Q$ (that is, an assignment $c \mapsto R(c)$ to each object $c$ of $\mathcal{C}$ of a subset $R(c)$ of $P(c) \times Q(c)$ which is functorial in the sense that for any arrow $f : c \to c'$ in $\mathcal{C}$, $P(f) \times Q(f)$ sends $R(c')$ to $R(c)$), is said to be $J$-functional from $P$ to $Q$ if it satisfies the following properties:

(i) for any $c \in \mathcal{C}$ and any $(x, y) \in P(c) \times Q(c)$, if $\{f : d \to c \mid (P(f)(x), Q(f)(y)) \in R(d)\} \in J(c)$ then $(x, y) \in R(c)$;

(ii) for any $c \in \mathcal{C}$ and any $(x, y), (x', y') \in R(c)$, if $x = x'$ then $\{f : d \to c \mid Q(f)(y) = Q(f)(y')\} \in J(c)$;

(iii) for any $c \in \mathcal{C}$ and any $x \in P(c)$, $\{f : d \to c \mid \exists y \in Q(d) \, (P(f)(x), y) \in R(d)\} \in J(c)$. 
Morphisms of sites

Theorem

Let \((\mathcal{C}, J)\) and \((\mathcal{C}', J')\) be small-generated sites, and let \(l : \mathcal{C} \to \text{Sh}(\mathcal{C}, J)\), \(l' : \mathcal{C}' \to \text{Sh}(\mathcal{C}', J')\) be the canonical functors (given by the composite of the relevant Yoneda embedding with the associated sheaf functor). Then, given a functor \(F : \mathcal{C} \to \mathcal{C}'\), the following conditions are equivalent:

(i) A induces a geometric morphism \(u : \text{Sh}(\mathcal{C}', J') \to \text{Sh}(\mathcal{C}, J)\) making the following square commutative:

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{C}' \\
\downarrow l & & \downarrow l' \\
\text{Sh}(\mathcal{C}, J) & \xrightarrow{u^*} & \text{Sh}(\mathcal{C}', J')
\end{array}
\]

(ii) The functor \(F\) is a morphism of sites \((\mathcal{C}, J) \to (\mathcal{C}', J')\) in the sense that it satisfies the following properties:

1. \(A\) sends every \(J\)-covering family in \(\mathcal{C}\) into a \(J'\)-covering family in \(\mathcal{C}'\).

2. Every object \(c'\) of \(\mathcal{C}'\) admits a \(J'\)-covering family

\[
c'_i \twoheadrightarrow c', \quad i \in I,
\]

by objects \(c'_i\) of \(\mathcal{C}'\) which have morphisms

\[
c'_i \twoheadrightarrow F(c_i)
\]

to the images under \(A\) of objects \(c_i\) of \(\mathcal{C}\).
Morphisms of sites

(3) For any objects $c_1, c_2$ of $\mathcal{C}$ and any pair of morphisms of $\mathcal{C}'$

$$f'_1 : c' \longrightarrow F(c_1), \quad f'_2 : c' \longrightarrow F(c_2),$$

there exists a $J'$-covering family

$$g'_i : c'_i \longrightarrow c', \quad i \in I,$$

and a family of pairs of morphisms of $\mathcal{C}$

$$f'_1 : b_i \longrightarrow c_1, \quad f'_2 : b_i \rightarrow c_2, \quad i \in I,$$

and of morphisms of $\mathcal{C}'$

$$h'_i : c'_i \longrightarrow F(b_i), \quad i \in I,$$

making the following squares commutative:
For any pair of arrows $f_1, f_2 : c \Rightarrow d$ of $C$ and any arrow of $C'$

$$f' : b' \longrightarrow F(c)$$

satisfying

$$F(f_1) \circ f' = F(f_2) \circ f',$$

there exist a $J'$-covering family

$$g'_i : b'_i \longrightarrow b', \quad i \in I,$$

and a family of morphisms of $C$

$$h_i : b_i \longrightarrow c, \quad i \in I,$$

satisfying

$$f_1 \circ h_i = f_2 \circ h_i, \quad \forall i \in I,$$

and of morphisms of $C'$

$$h'_i : b'_i \longrightarrow F(b_i), \quad i \in I,$$

making commutative the following squares:

$$\begin{array}{ccc}
  b'_i & \xrightarrow{g'_i} & b' \\
  \downarrow{h'_i} & & \downarrow{f'} \\
  F(b_i) & \xrightarrow{F(h_i)} & F(c)
\end{array}$$
Morphisms of sites

If $F$ is a morphism of sites $(C, J) \rightarrow (D, K)$, we denote by $\text{Sh}(F) : \text{Sh}(D, K) \rightarrow \text{Sh}(C, J)$ the geometric morphism which it induces.

Remarks

- The above characterization of morphisms of sites is equivalent to that given by Mike Shulman in his paper “Exact completions and small sheaves”, which specifies that a functor is a morphism of sites when it is cover-preserving and covering-flat (in the sense that for any finite diagram $D$ in $C$ every cone over an object of the form $F(c)$ factors locally through the $F$-image of a cone over $D$), and also proves the above theorem by using his definition.

- If $(C, J)$ and $(D, K)$ are cartesian sites (that is, $C$ and $D$ are cartesian categories) then a functor $C \rightarrow D$ which is cartesian and sends $J$-covering families to $K$-covering families is a morphism of sites $(C, J) \rightarrow (D, K)$.

- If $J$ and $K$ are subcanonical then a geometric morphism $g : \text{Sh}(D, K) \rightarrow \text{Sh}(C, J)$ is of the form $\text{Sh}(f)$ for some $f$ if and only if the inverse image functor $g^*$ sends representables to representables; if this is the case then $f$ is isomorphic to the restriction of $g^*$ to the full subcategories of representables.
Recall that a comorphism of sites \((\mathcal{D}, K) \to (\mathcal{C}, J)\) is a functor \(\pi : \mathcal{D} \to \mathcal{C}\) such that for any \(d \in \mathcal{D}\) and any \(J\)-covering sieve \(S\) on \(\pi(d)\) there is a \(K\)-covering sieve \(R\) on \(d\) such that \(\pi(R) \subseteq S\).

**Proposition**

*Every comorphism of sites* \(\pi : \mathcal{D} \to \mathcal{C}\) *induces a flat and* \(J\)-*continuous functor* \(A_\pi : \mathcal{C} \to \text{Sh}(\mathcal{D}, K)\) *given by*

\[
A_\pi(c) = a_K(\text{Hom}_\mathcal{C}(\pi(-), c))
\]

*and hence a geometric morphism*

\[
f : \text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{C}, J)
\]

*with inverse image* \(f^*(F) \cong a_K(F \circ \pi)\) *for any* \(J\)-*sheaf* \(F\) *on* \(\mathcal{C}\).*
Kan extensions

The direct and image functors of geometric morphisms induced by morphisms or comorphisms of sites can be naturally described in terms of Kan extensions.

Recall that, given a functor \( f : \mathcal{C} \to \mathcal{D} \),

- the right Kan extension \( \text{Ran}_{f^{\text{op}}} \) along \( f^{\text{op}} \), which is right adjoint to the functor \( f^{*} : [\mathcal{D}^{\text{op}}, \mathbf{Set}] \to [\mathcal{C}^{\text{op}}, \mathbf{Set}] \), is given by the following formula:

\[
\text{Ran}_{f^{\text{op}}}(F)(b) = \lim_{\phi : fa \to b} F(a),
\]

where the limit is taken over the opposite of the comma category \((f \downarrow b)\).

- The left adjoint to \( f^{*} \) is the left Kan extension \( \text{Lan}_{f^{\text{op}}} \) along \( f^{\text{op}} \), which is left adjoint to \( f^{*} \), is given by the following formula:

\[
\text{Lan}_{f^{\text{op}}}(F)(b) = \lim_{\phi : b \to fa} F(a),
\]

where the colimit is taken over the opposite of the comma category \((b \downarrow f)\).

Proposition

(i) Let $F : (C, J) \to (D, K)$ be a morphism of small-generated sites. Then

- the direct image $\text{Sh}(F)_*$ of the geometric morphism
  $$\text{Sh}(F) : \text{Sh}(D, K) \to \text{Sh}(C, J)$$
  induced by $F$ is given by the restriction to sheaves of $F^*$;
- the inverse image $\text{Sh}(F)^*$ of $\text{Sh}(F)$ is given by
  $$a_{K} \circ \text{Lan}_{F^\text{op}} \circ i_J,$$
where $\text{Lan}_{F^\text{op}}$ is the left Kan extension and $i_J$ is the inclusion $\text{Sh}(C, J) \hookrightarrow [C^{\text{op}}, \text{Set}]$.

(ii) Let $F : (D, K) \to (C, J)$ be a comorphism of small-generated sites. Then

- the direct image $(C_F)_*$ of the geometric morphism
  $$C_F : \text{Sh}(D, K) \to \text{Sh}(C, J)$$
  induced by $F$ is given by the restriction to sheaves of the right Kan extension $\text{Ran}_{F^\text{op}}$;
- the inverse image $(C_F)^*$ of $C_F$ is given by
  $$a_J \circ F^* \circ i_K,$$
where $i_K$ is the inclusion $\text{Sh}(D, K) \hookrightarrow [D^{\text{op}}, \text{Set}]$. 
Unifying morphisms and comorphisms of sites

In order to better contextualize the role of morphisms and of comorphisms of sites, we will now briefly review the philosophy of toposes as ‘bridges’, which also inspires all the other results presented in this course.

In fact, we shall unify the notions of morphism and comorphisms of sites by interpreting them as two fundamentally different ways of describing morphisms of toposes which correspond to each other under a ‘bridge’.

More specifically, morphisms of sites provide an ‘algebraic’ perspective on morphisms of toposes, while comorphisms of sites provide a ‘geometric’ perspective on them.
Topos-theoretic invariants

- By a **topos-theoretic invariant** we mean any notion which is invariant under categorical equivalence of toposes.

- The notion of a **geometric morphism** of toposes is a fundamental invariant, which has notably allowed to build **general comology theories** starting from the categories of internal abelian groups or modules in toposes. In particular, the topos-theoretic viewpoint has allowed Grothendieck to refine and enrich the study of cohomology, up to the so-called ‘six-operation formalism’. The cohomological invariants have had a tremendous impact on the development of modern Algebraic Geometry and beyond.

- On the other hand, also **homotopy-theoretic invariants** such as the fundamental group and the higher homotopy groups can be defined as invariants of toposes.

- Still, these are by no means the only invariants that one can consider on toposes: indeed, there are **infinitely many invariants** of toposes (of algebraic, logical, geometric or whatever nature), the notion of identity for toposes being simply categorical equivalence.
Toposes as *bridges*

- In the topos-theoretic study of theories or ‘concrete’ mathematical contexts, the latter are represented by sites (of definition of their classifying topos or of some other topos naturally attached to them).

- Grothendieck toposes can be effectively used as ‘bridges’ for transferring notions, properties and results across them:

  \[ \mathcal{E}_T \cong \mathcal{E}_{T'} \]

  \[ \mathbb{T} \to \mathbb{T}' \]

- The *transfer of information* takes place by expressing topos-theoretic *invariants* in terms of the different sites of definition (or, more generally, presentations) for the given topos.

- As such, different properties (resp. constructions) arising in the context of the two presentations are seen to be different *manifestations* of a *unique* property (resp. construction) lying at the topos-theoretic level.
The ‘bridge’ technique

- **Decks** of ‘bridges’: **Morita-equivalences** (that is, equivalences between different presentations of a given topos, or more generally morphisms or other kinds of relations between toposes)

- **Arches** of ‘bridges’: **Site characterizations for topos-theoretic invariants** (or more generally ‘unravelings’ of topos-theoretic invariants in terms of concrete representations of the relevant topos)

For example, this ‘bridge’ yields a logical equivalence between the ‘concrete’ properties $P_{(C,J)}$ and $Q_{(D,K)}$, interpreted in this context as manifestations of a unique property $I$ lying at the level of the topos.
Toposes as *bridges*

- This methodology is technically effective because the relationship between a topos and its representations is often very natural, enabling us to transfer invariants across different representations.

- On the other hand, the ‘bridge’ technique is highly non-trivial, in the sense that it often yields deep and surprising results. This is due to the fact that a given invariant can manifest itself in significantly different ways in the context of different presentations.

- The level of generality represented by topos-theoretic invariants is ideal to capture several important features of mathematical theories and constructions.
Relating morphisms and comorphisms of sites

The inspiration for our constructions is provided by the following result:

Proposition

Let \((\mathcal{C}, J)\) and \((\mathcal{D}, K)\) be small-generated sites, and \((F : \mathcal{C} \to \mathcal{D} \dashv G : \mathcal{D} \to \mathcal{C})\) adjoint functors. Then

(i) \(G\) is a morphism of sites \((\mathcal{D}, K) \to (\mathcal{C}, J)\) if and only if \(F\) is a comorphism of sites \((\mathcal{C}, J) \to (\mathcal{D}, K)\).

(ii) In the situation of (i), the geometric morphism \(C_F\) induced by \(F\) coincides with the geometric morphism \(\text{Sh}(G)\) induced by \(G\).

The key idea is to replace the given sites of definition with Morita-equivalent ones in such a way that every morphism (resp. comorphism) of sites acquires a left (resp. right) adjoint, not necessarily in the classical categorial sense but in the weaker topos-theoretic sense of the associated comma categories having equivalent associated toposes.
From morphisms to comorphisms of sites

We shall turn a morphism of sites into a comorphism of sites by replacing the original codomain site with a site related to it by a morphism inducing an equivalence of toposes such that the composite of the given morphism of sites with it admits a left adjoint; this left adjoint will then be a comorphism of sites inducing the same geometric morphism (by the above proposition).

We shall denote by \((F \downarrow G)\), for two functors \(F : \mathcal{A} \to \mathcal{C}\) and \(G : \mathcal{B} \to \mathcal{C}\), the comma category whose objects are the triplets \((a, b, \alpha)\) where \(a \in \mathcal{A}\), \(b \in \mathcal{B}\) and \(\alpha\) is an arrow \(F(a) \to G(b)\) in \(\mathcal{C}\) (and whose arrows are defined in the obvious way).

In particular, given a functor \(F : \mathcal{C} \to \mathcal{D}\), the objects of \((1_\mathcal{D} \downarrow F)\) are triplets of the form \((d, c, \alpha : d \to F(c))\) where \(c \in \mathcal{C}\), \(d \in \mathcal{D}\) and \(\alpha\) is an arrow in \(\mathcal{D}\).
From morphisms to comorphisms of sites

Theorem
Let \( F : (\mathcal{C}, J) \to (\mathcal{D}, K) \) be a morphism of small-generated sites. Let \( i_F \) be the functor \( \mathcal{C} \to (1 \downarrow F) \) sending any object \( c \) of \( \mathcal{C} \) to the triplet \( (F(c), c, 1_{F(c)}) \) (and acting on arrows in the obvious way), and \( \pi_C : (1 \downarrow F) \to \mathcal{C} \) and \( \pi_D : (1 \downarrow F) \to \mathcal{D} \) the canonical projection functors. Let \( \tilde{K} \) be the Grothendieck topology on \( (1 \downarrow F) \) whose covering sieves are those whose image under \( \pi_D \) is \( K \)-covering. Then

(i) \( \pi_C \dashv i_F, \pi_D \circ i_F = F, i_F \) is a morphism of sites \( (\mathcal{C}, J) \to ((1 \downarrow F), \tilde{K}) \) and \( c_F := \pi_C \) is a comorphism of sites \( (1 \downarrow F), \tilde{K}) \to (\mathcal{C}, J) \);
(ii) \( \pi_D : ((1 \downarrow F), \tilde{K}) \to (\mathcal{D}, K) \) is both a morphism of sites and a comorphism of sites inducing equivalences

\[
\pi_D : \text{Sh}((1 \downarrow F), \tilde{K}) \to \text{Sh}(\mathcal{D}, K)
\]

and

\[
\text{Sh}(\pi_D)^{-1} \text{Sh}(\mathcal{D}, K) \to \text{Sh}((1 \downarrow F), \tilde{K})
\]

which are quasi-inverse to each other and make the following triangle commute:

\[
\text{Sh}((1 \downarrow F), \tilde{K}) \xrightarrow{\sim} \text{Sh}(\mathcal{D}, K) \xrightarrow{\text{Sh}(\pi_D)^{-1}} \text{Sh}(\pi_D)
\]

\[
\text{Sh}(\pi_D)^{-1} \text{Sh}(\mathcal{D}, K) \to \text{Sh}((1 \downarrow F), \tilde{K}) \xleftarrow{C_{\pi_C}} \text{Sh}((1 \downarrow F), \tilde{K})
\]

\[
\text{Sh}(\mathcal{C}, J) \xrightarrow{\text{Sh}(F)^{-1}} \text{Sh}(\pi_D) \xrightarrow{\text{Sh}(\pi_D)^{-1}} \text{Sh}(\mathcal{D}, K)
\]
From comorphisms to morphisms of sites

Below, we shall abbreviate by $\hat{D}$ the category of presheaves on a small category $D$.

**Theorem**

Let $F : (\mathcal{D}, K) \to (\mathcal{C}, J)$ be a comorphism of small-generated sites. Let $\pi'_C : (F \downarrow 1_{\mathcal{C}}) \to \mathcal{C}$ and $\pi'_D : (F \downarrow 1_{\mathcal{C}}) \to \mathcal{D}$ be the canonical projection functors and $j_F : \mathcal{D} \to (F \downarrow 1_{\mathcal{C}})$ the functor sending any object $d$ of $\mathcal{D}$ to the triplet $(d, F(d), 1_{F(d)})$. Let $K$ be the Grothendieck topology on $(F \downarrow 1_{\mathcal{C}})$ whose covering families are those which are sent by $\pi'_D$ to $K$-covering families. Then

(i) $j_F \dashv \pi'_D$, $\pi'_C \circ j_F = F$, $\pi'_C$ is a comorphism of sites $(F \downarrow 1_{\mathcal{C}}, K) \to (\mathcal{C}, J)$ and $j_F$ is a (full and faithful) comorphism and dense morphism of sites $(\mathcal{D}, K) \to (F \downarrow 1_{\mathcal{C}}, K)$;

(ii) $\pi'_D$ is both a morphism and a comorphism of sites $((F \downarrow 1_{\mathcal{C}}), K) \to (\mathcal{D}, K)$ inducing equivalences

$$C_{\pi'_D} : \text{Sh}((F \downarrow 1_{\mathcal{C}}), K) \to \text{Sh}(\mathcal{D}, K)$$

and

$$\text{Sh}(\pi'_D) : \text{Sh}(\mathcal{D}, K) \to \text{Sh}((F \downarrow 1_{\mathcal{C}}), K)$$

which are quasi-inverse to each other and make the following triangle commute:

$$\text{Sh}((F \downarrow 1_{\mathcal{C}}), K) \xrightarrow{C_{\pi'_D}} \text{Sh}(\mathcal{D}, K) \xleftarrow{\sim} \text{Sh}(\pi'_D) \cong \text{Sh}(F, K)$$

$$\text{Sh}(\mathcal{D}, K) \xleftarrow{C_{\pi'_C}} \text{Sh}((F \downarrow 1_{\mathcal{C}}), K) \xrightarrow{\sim} \text{Sh}(\mathcal{C}, J) \xleftarrow{C_F} \text{Sh}(\mathcal{D}, K)$$
(iii) With the comorphism of sites $F : (\mathcal{D}, K) \to (\mathcal{C}, J)$ we can associate the morphism of sites

$$m_F : (\mathcal{C}, J) \to (\hat{\mathcal{D}}, \hat{K})$$

sending an object $c$ of $\mathcal{C}$ to the presheaf $\text{Hom}_C(F(\_), c)$ and $\hat{K}$ is the extension of the Grothendieck topology $K$ along the Yoneda embedding $\mathcal{D} \to \hat{\mathcal{D}}$, which induces a geometric morphism $\text{Sh}(m_F)$ making the following triangle commute:
Theorem
Let \((\mathcal{C}, J)\) and \((\mathcal{D}, K)\) be small-generated sites.

(i) Let \(F : (\mathcal{C}, J) \to (\mathcal{D}, K)\) be a morphism of sites, with corresponding comorphism of sites \(c_F : ((1_D \downarrow F), \tilde{K}) \to (\mathcal{C}, J)\) as above. Let \(\pi_D : ((1_D \downarrow F), \tilde{K}) \to (\mathcal{D}, K)\) be the canonical projection functor, and let

\[ w_F : (1_D \downarrow F) \to (c_F \downarrow 1_D) \]

be the functor \(j_{c_F}\), sending an object \(A\) of \((1_D \downarrow F)\) to the object \((A, c_F(A), 1_{c_F(A)} : c_F(A) \to c_F(A))\). Then \(w_F\) is both a (full and faithful) comorphism and a dense morphism of sites \(((1_D \downarrow F), \tilde{K}) \to ((c_F \downarrow 1_D), \tilde{K})\) satisfying the relation \(\pi'''_D \circ w_F = \pi_D\) and inducing an equivalence relating \(F\) and \(c_F\), which makes the following diagram commute (where \(\pi'''_D\) denotes the canonical projection functor \((c_F \downarrow 1_D) \to \mathcal{D})\):

\[
\begin{array}{ccc}
\text{Sh}(\mathcal{D}, K) & \xrightarrow{\sim} & \text{Sh}(\mathcal{D}, K) \\
C_{\pi'''_D} \uparrow \Phi & = & C_{\pi'''_D} \downarrow \text{Sh}(\pi'''_D) \\
\text{Sh}((c_F \downarrow 1_D), \tilde{K}) & \xleftarrow{\sim} & \text{Sh}((1_D \downarrow F), \tilde{K}) \\
C_{w_F} \cong \text{Sh}(\pi'_D \downarrow F) & & C_{c_F} \cong \text{Sh}(\pi'_D \downarrow F) \\
\end{array}
\]
(ii) Let $G : (\mathcal{D}, K) \to (\mathcal{C}, J)$ be a comorphism of sites, with corresponding morphism of sites $m_G : (\mathcal{C}, J) \to (\hat{\mathcal{D}}, \hat{K})$ as above. Let

$$z_G : (G \downarrow 1_C) \to (1_{\hat{\mathcal{D}}} \downarrow m_G)$$

be the functor sending any object $(d, c, \alpha : G(d) \to c)$ of $(G \downarrow 1_C)$ to the object $(y_{\mathcal{D}}(d), c, \bar{\alpha} : y_{\mathcal{D}}(d) \to m_G(c))$ of $(1_{\hat{\mathcal{D}}} \downarrow m_G)$, where $\bar{\alpha}$ is the arrow corresponding to the element $\alpha$ of $m_G$ via the Yoneda Lemma. Then $z_G$ is both a (full and faithful) comorphism and a dense morphism of sites $((G \downarrow 1_C), \mathcal{K}) \to ((1_{\hat{\mathcal{D}}} \downarrow m_G), \tilde{\mathcal{K}})$ satisfying the relation $\pi_{\hat{\mathcal{D}}} \circ z_G = y_{\mathcal{D}} \circ \pi'_{\hat{\mathcal{D}}}$ and inducing an equivalence relating $G$ and $m_G$, which makes the following diagram commute:
Bridging morphisms and comorphisms of sites

We shall call a functor which both a morphism and a comorphism of sites a **bimorphism of sites**.

The above theorem shows that the relationship between a morphism $F$ (resp. comorphism $G$) of sites and the associated comorphism $c_F$ (resp. morphism $m_G$) of sites is captured by the equivalence

$$\text{Sh}(((1_D \downarrow F), \tilde{K}) \simeq \text{Sh}((c_F \downarrow 1_D), \overline{\tilde{K}})$$

(resp.

$$\text{Sh}((G \downarrow 1_C), \overline{\tilde{K}}) \simeq \text{Sh}((1_{\overline{D}} \downarrow m_G), \tilde{K}))$$

of toposes over $\text{Sh}(C, J)$ induced by the bimorphism of sites $w_F$ (resp. $z_G$) over $C$.

Our theorem then tells us that $F$ and $c_F$ (resp. $G$ and $m_G$) are not adjoint to each other in a concrete sense (that is, at the level of sites), since they are not defined between a pair of categories, nor the categories $(1_D \downarrow F)$ and $(c_F \downarrow 1_D)$ (resp. the categories $(G \downarrow 1_C)$ and $(1_{\overline{D}} \downarrow m_G)$) are equivalent in general; nonetheless, they become ‘abstractly’ adjoint in the world of toposes since toposes naturally attached to such categories are equivalent.
The dual adjunction

Definition
Let \((C, J)\) be a small-generated site.

(a) The category \(\text{Mor}_{(C, J)}\) has as objects the morphisms of sites from \((C, J)\) to a small generated site \((D, K)\) and as arrows

\[
(F : (C, J) \to (D, K)) \to (F' : (C, J) \to (D', K'))
\]

between any two such morphisms the geometric morphisms

\[
f : \text{Sh}(D', K') \to \text{Sh}(D, K)
\]
such that \(\text{Sh}(F) \circ f \cong \text{Sh}(F'):\)

\[
\begin{array}{ccc}
\text{Sh}(C, J) & \xleftarrow{\text{Sh}(F)} & \text{Sh}(D, K) \\
\downarrow{\text{Sh}(F')} & & \downarrow{i} \\
\text{Sh}(D', K') & & \text{Sh}(D', K')
\end{array}
\]

(b) The category \(\text{Com}_{(C, J)}\) has as objects the comorphisms of sites from a small-generated site \((D, K)\) to \((C, J)\) and as arrows

\[
(U : (D, K) \to (C, J)) \to (U' : (D', K') \to (C, J))
\]

between any two such comorphisms the geometric morphisms

\[
g : \text{Sh}(D, K) \to \text{Sh}(D', K')
\]
such that \(C_{U'} \circ g \cong C_U:\)

\[
\begin{array}{ccc}
\text{Sh}(D, K) & \xrightarrow{C_U} & \text{Sh}(C, J) \\
\downarrow{g} & & \downarrow{C_{U'}} \\
\text{Sh}(D', K') & & \text{Sh}(D', K')
\end{array}
\]
The dual adjunction

The assignments $F \mapsto c_F$ and $G \mapsto m_G$ introduced above naturally define two functors

$$C : (\text{Mor}(C,J))^{\text{op}} \to \text{Com}(C,J)$$

and

$$M : \text{Com}(C,J) \to (\text{Mor}(C,J))^{\text{op}}.$$

Theorem

The functors

$$C : (\text{Mor}(C,J))^{\text{op}} \to \text{Com}(C,J)$$

and

$$M : \text{Com}(C,J) \to (\text{Mor}(C,J))^{\text{op}}$$

are (2-categorically) adjoint (C on the right and M on the left) and quasi-inverse to each other.
From comorphisms of sites to fibrations

The following result shows that one can naturally associate with a comorphism of sites a fibration inducing the same geometric morphism.

**Definition**
The fibration of generalized elements of a functor \( F : \mathcal{D} \to \mathcal{C} \) is the canonical projection functor \( \pi^F_C : (1_C \downarrow F) \to \mathcal{C} \).

**Theorem**
Let \( F : (\mathcal{D}, K) \to (\mathcal{C}, J) \) be a comorphism of small-generated sites, \( i^F_F \) the canonical functor \( \mathcal{D} \to (1_C \downarrow F) \) and \( K^i^F_F \) the Grothendieck topology on \( (1_C \downarrow F) \) whose covering sieves are those whose pullback along any arrow whose domain is an object of the form \( i^F_F(d) \) contains the image under \( i^F_F \) of a \( K \)-covering sieve on \( d \). Let \( \pi^F_D \) and \( \pi^F_C \) be the canonical projections from \( (1_C \downarrow F) \) respectively to \( \mathcal{C} \) and \( \mathcal{D} \). Then

(i) \( \pi^F_D \circ i^F_F = \pi^F_C \circ i^F_F = F \), \( \pi^F_C \) is a comorphism of sites \( ((1_C \downarrow F), K^i^F_F) \to (\mathcal{C}, J) \) and \( \pi^F_D \) is a comorphism of sites \( ((1_C \downarrow F), K^i^F_F) \to (\mathcal{D}, K) \);

(ii) \( i^F_F \) is both a (full and faithful) comorphism of sites and a dense morphism of sites \( (\mathcal{D}, K) \to ((1_C \downarrow F), K^i^F_F) \) inducing equivalences

\[
C_{i^F_F} : \text{Sh}(\mathcal{D}, K) \to \text{Sh}((1_C \downarrow F), K^i^F_F)
\]

and

\[
\text{Sh}(i^F_F) : \text{Sh}((1_C \downarrow F), K^i^F_F) \to \text{Sh}(\mathcal{D}, K)
\]

which are quasi-inverse to each other and make the following triangle commute:

\[
\begin{array}{ccc}
\text{Sh}((1_C \downarrow F), K^i^F_F) & \xrightarrow{\sim} & \text{Sh}(\mathcal{D}, K) \\
\downarrow C_{i^F_F} & & \downarrow C_{i^F_F} \\
\text{Sh}(\mathcal{C}, J) & \xrightarrow{\text{Sh}(i^F_F)} & \text{Sh}(\mathcal{D}, K)
\end{array}
\]
Fibrations as comorphisms of sites

In the converse direction, every fibration can be naturally regarded as a comorphism of sites, as follows.

Recall that, given a functor $A : C \to D$ and a Grothendieck topology $K$ in $D$, there is a smallest Grothendieck topology on $C$ which makes $A$ a comorphism of sites to $(D, K)$. This topology, which we denote by $M_A^K$, is generated by the (pullback-stable) family of sieves of the form $S^A_R := \{ f : \text{dom}(f) \to c \mid A(f) \in R \}$ for an object $c$ of $C$ and a $K$-covering sieve $R$ on $A(c)$.

**Proposition**

If $A$ is a fibration, the topology $M_A^K$ admits the following simpler description: a sieve $R$ is $M_A^K$-covering if and only if the collection of cartesian arrows in $R$ is sent by $A$ to a $K$-covering family.

This point of view on fibrations was inspired by Jean Giraud’s construction of the classifying topos of a stack (see the forthcoming joint work with Riccardo Zanfa).

**Proposition**

For any Grothendieck topology $K$ on $D$, every morphism of fibrations $(A : C \to D) \to (A' : C' \to D)$ yields a comorphism of sites $(C, M_A^K) \to (C', M_{A'}^K)$.

Continuous functors and weak morphisms of toposes

Relative cofinality

Denseness conditions

Characterization of invariant properties of morphisms

Characterizations in terms of comorphisms of sites

Local morphisms

Weak morphisms of toposes

Definition

A weak morphism of toposes \( f : \mathcal{E} \to \mathcal{F} \) is a pair of adjoint functors \((f^* \dashv f_*)\).

As in the case of geometric morphism, we call \( f_* \) the direct image of \( f \) and \( f^* \) the inverse image of \( f \).

Proposition

Let \( i : \mathcal{F} \hookrightarrow \mathcal{E} \) be the geometric inclusion of a subtopos \( \mathcal{F} \) of a Grothendieck topos \( \mathcal{E} \) into \( \mathcal{E} \), and let \( f : \mathcal{G} \to \mathcal{E} \) be a weak morphism from a Grothendieck topos \( \mathcal{G} \). Then the following conditions are equivalent:

(i) The weak morphism \( f \) factors through \( i \);

(ii) The direct image \( f_* \) takes values in \( \mathcal{F} \) (that is, factors through \( i_* \));

(iii) The inverse image \( f^* \) factors (necessarily uniquely up to isomorphism) through \( i^* \).

Corollary

Let \( A : \mathcal{C} \to \mathcal{E} \) be a functor from an essentially small category \( \mathcal{C} \) to a Grothendieck topos \( \mathcal{E} \), and \( J \) be a Grothendieck topology on \( \mathcal{C} \). Then the following conditions are equivalent:

(i) The weak morphism \((L_A \dashv R_A)\) factors through the canonical geometric inclusion \( i : \text{Sh}(\mathcal{C}, J) \hookrightarrow [\mathcal{C}^{\text{op}}, \text{Set}] \);

(ii) The functor \( R_A \) takes values in \( \text{Sh}(\mathcal{C}, J) \);

(iii) The functor \( L_A \) factors (necessarily uniquely up to isomorphism) through the associated sheaf functor \( a_J : [\mathcal{C}^{\text{op}}, \text{Set}] \to \text{Sh}(\mathcal{C}, J) \).
The above result motivates the following definition:

**Definition**

(a) Given a small-generated site \((C, J)\), we say that a functor \(A : C \to \mathcal{E}\) is \(J\)-continuous if the hom functor \(R_A : \mathcal{E} \to [C^{\text{op}}, \text{Set}]\) takes values into \(\text{Sh}(C, J)\) (equivalently, if the functor \(L_A : [C^{\text{op}}, \text{Set}] \to \mathcal{E}\) factors through \(a_J : [C^{\text{op}}, \text{Set}] \to \text{Sh}(C, J)\)).

(b) Given small-generated sites \((C, J)\) and \((D, K)\), a functor \(A : C \to D\) is said to be \((J, K)\)-continuous if \(l' \circ A\) is \(J\)-continuous, where \(l'\) is the canonical functor \(D \to \text{Sh}(D, K)\).

The following proposition shows that the above definition is equivalent to Grothendieck’s notion of continuous functor:

**Proposition**

Let \((C, J)\) and \((D, K)\) be small-generated sites and \(A : C \to D\) a functor. Then the following conditions are equivalent:

(i) \(A\) is \((J, K)\)-continuous.

(ii) The functor

\[ D_A := (- \circ A^{\text{op}}) : [D^{\text{op}}, \text{Set}] \to [C^{\text{op}}, \text{Set}] \]

restricts to a functor \(\text{Sh}(D, K) \to \text{Sh}(C, J)\).
Classifying weak morphisms of toposes

Let $[\mathcal{C}, \mathcal{E}]_J$ be the full subcategory of $[\mathcal{C}, \mathcal{E}]$ on the $J$-continuous functors.

**Proposition**

Let $\mathcal{C}$ a locally small category and $\mathcal{E}$ a Grothendieck topos.

(i) There is an equivalence

$$\text{Wmor}(\mathcal{E}, [\mathcal{C}^{\text{op}}, \text{Set}]) \simeq [\mathcal{C}, \mathcal{E}]$$

sending a weak morphism $f = (f^* \dashv f_*)$ to the functor $f^* \circ y_C$.

(ii) For any Grothendieck topology $J$ on $\mathcal{C}$ making $(\mathcal{C}, J)$ a small-generated site, the above equivalence restricts to an equivalence

$$\text{Wmor}(\mathcal{E}, \text{Sh}(\mathcal{C}, J)) \simeq [\mathcal{C}, \mathcal{E}]_J$$

sending a weak morphism $g = (g^* \dashv g_*)$ to the functor $g^* \circ l$. 

Weak morphisms of sites

These results motivate the following

Definition
Let \((C, J)\) and \((D, K)\) be small-generated sites. A functor \(F : C \to D\) is said to be a weak morphism of sites if it is \((J, K)\)-continuous.

Note that this notion generalizes that of morphism of sites; indeed, as morphisms of sites induce geometric morphisms of toposes, so weak morphisms of sites induce weak morphisms of toposes:

Proposition
Any weak morphism \(F : (C, J) \to (D, K)\) of small-generated sites induces a weak geometric morphism \(\text{Sh}(F) : \text{Sh}(D, K) \to \text{Sh}(C, J)\) such that the following diagram commutes:

\[
\begin{align*}
  C \xrightarrow{F} & D \\
  \downarrow l & \downarrow l' \\
  \text{Sh}(C, J) \xrightarrow{\text{Sh}(F)^*} & \text{Sh}(D, K)
\end{align*}
\]

Conversely, any weak geometric morphism \(f = (f^* \dashv f_*)\) such that \(f^* \circ l\) factors through \(l'\) is induced by a (necessarily unique, if \(K\) is subcanonical) weak morphism of sites \((C, J) \to (D, K)\).

Proposition

Let $(\mathcal{C}, J)$ and $(\mathcal{D}, K)$ be small-generated sites and $\mathcal{E}$ a Grothendieck topos. Then

(i) A functor $A: \mathcal{C} \to \mathcal{E}$ is $J$-continuous if and only if for any $J$-covering sieve $S$ on an object $c$

$$A(c) = \lim_{f: d \to c \in S} A(d)$$

for each $J$-covering sieve $S$ on an object $c$ (where the colimit is indexed by the category $\int S$ of elements of $S$).

(ii) A functor $A: \mathcal{C} \to \mathcal{D}$ is $(J, K)$-continuous if and only if for any $J$-covering sieve $S$ on an object $c$ the canonical cocone with vertex $A(c)$ on the diagram $\{A(\text{dom}(f)) \mid f \in S\}$ indexed over $\int S$ is sent by $l'$ to a colimit in the topos $\text{Sh}(\mathcal{D}, K)$.

(iii) Every $J$-continuous functor $A: \mathcal{C} \to \mathcal{E}$ is $J$-continuous in the sense of Mac Lane and Moerdijk (that is, sends $J$-covering families to epimorphic families), and the converse is true if $A$ is flat (but not in general). More generally, every $(J, K)$-continuous functor $(\mathcal{C}, J) \to (\mathcal{D}, K)$ is cover-preserving, and every morphism of sites $(\mathcal{C}, J) \to (\mathcal{D}, K)$ is $(J, K)$-continuous.
The above proposition suggests that the property of $J$-continuity could be interpreted as a sort of cofinality condition. Indeed, if $A$ is $J$-continuous then in particular $A$ sends any $J$-covering sieve $S$ on an object $c$ of $C$ to an epimorphic family and hence $A(c)$ is the colimit of the cocone under the diagram whose vertices are the objects of the form $A(d)$ where $d$ is the domain of an arrow $f : d \to c$ in $S$ and whose arrows are all the arrows in $\mathcal{E}$ over $A(c)$ between such objects. So the condition for $A$ to be $J$-continuous amounts precisely to the assertion that $A$ be $J$-continuous and that this colimit be equal to the colimit $\lim_{\longrightarrow f : d \to c \in S} A(d)$.

In order to formally express continuity as a form of cofinality, we are going to introduce relative cofinality conditions.
Relative cofinality

Proposition

Let $(C, J)$ be a small-generated site and $F : A \to C$ and $F' : A' \to C$ two functors to $C$ related by a functor $\xi : A \to A'$ and a natural transformation $\alpha : F \to F' \circ \xi$. Let $R_c$ (resp. $R'_c$), for any $c \in C$, be the equivalence relations on the objects of the category $(c \downarrow F)$ (resp. of $(c \downarrow F')$) given by the relation of belonging to the same connected component.

Then the canonical arrow

$$\tilde{\alpha} : \text{colim}_{[C^{op}, \text{Set}]}(y_C \circ F) \to \text{colim}_{[C^{op}, \text{Set}]}(y_C \circ F')$$

is sent by $a_J$ to an isomorphism

$$a_J(\tilde{\alpha}) : \text{colim}_{\text{Sh}(C, J)}(l \circ F) \to \text{colim}_{\text{Sh}(C, J)}(l \circ F')$$

if and only if the pair $(\xi, \alpha)$ satisfies the following ‘cofinality’ conditions:

(i) For any object $c$ of $C$ and any arrow $y : c \to F'(a')$ in $C$ there are a $J$-covering family $\{f_i : c_i \to c \mid i \in I\}$ and for each $i \in I$ an object $a_i$ of $A$ and an arrow $y_i : c_i \to F(a_i)$ such that

$$(y \circ f_i, \alpha(a_i) \circ y_i) \in R'_{c_i}.$$ 

(ii) For any object $c$ of $C$ and any arrows $x : c \to F(a)$ and $x' : c \to F(b)$ in $C$ such that $(\alpha(a) \circ x, \alpha(b) \circ x') \in R'_c$ there is a $J$-covering family $\{f_i : c_i \to c \mid i \in I\}$ such that $(x \circ f_i, x' \circ f_i) \in R_{c_i}$ for each $i \in I$. 
J-cofinal functors

It is interesting to apply the proposition in two notable particular cases:

1. \( F = \xi : \mathcal{A} \to \mathcal{C} \), \( F' = 1_{\mathcal{C}} \), \( \alpha \) is the identity.
2. \( F' \) is the forgetful functor \( U_{c_0} : \mathcal{C}/c_0 \to \mathcal{C} \) for an object \( c_0 \) of \( \mathcal{C} \), \( \xi \) is a cocone \( \{ \xi_a : F(a) \to c_0 \mid a \in \mathcal{A} \} \) under the functor \( F \) with vertex \( c_0 \) and \( \alpha \) is the identity.

Formulating the thesis of the proposition in these particular cases leads us to introduce the following

**Definition**

Given a small-generated site \((\mathcal{C}, J)\), a functor \( F : \mathcal{A} \to \mathcal{C} \) is said to be **J-cofinal** if the following conditions are satisfied:

(i) For any object \( c \) of \( \mathcal{C} \) there are a \( J \)-covering family \( \{ f_i : c_i \to c \mid i \in I \} \) and for each \( i \in I \) an object \( a_i \) of \( \mathcal{A} \) and an arrow \( y_i : c_i \to F(a_i) \).

(ii) For any object \( c \) of \( \mathcal{C} \) and any arrows \( x : c \to F(a) \) and \( x' : c \to F(b) \) in \( \mathcal{C} \) there is a \( J \)-covering family \( \{ f_i : c_i \to c \mid i \in I \} \) such that \( x \circ f_i \) and \( x' \circ f_i \) belong to the same connected component of the category \( (c_i \downarrow F) \) for each \( i \in I \).
Two corollaries

The proposition thus yields the following two results:

**Corollary**

Let \((\mathcal{C}, J)\) be a small-generated site and \(F : \mathcal{A} \to \mathcal{C}\) a functor. Then \(F\) is \(J\)-cofinal if and only if the canonical arrow

\[
\text{colim}_{\text{Sh}(\mathcal{C}, J)}(I \circ F) \to 1_{\text{Sh}(\mathcal{C}, J)}
\]

is an isomorphism.

**Corollary**

Let \(D : \mathcal{A} \to \mathcal{C}\) be a functor and \(\xi\) a cocone \(\{\xi_a : D(a) \to c_0 \mid a \in \mathcal{A}\}\) under \(D\) with vertex \(c_0\). Let \(U_{c_0}\) be the forgetful functor \(\mathcal{C}/c_0 \to \mathcal{C}\), \(J_{c_0}\) the Grothendieck topology on \(\mathcal{C}/c_0\) whose covering sieves are precisely those whose image under \(U_{c_0}\) is \(J\)-covering and \(D_\xi : \mathcal{A} \to \mathcal{C}/c_0\) the canonical lift of \(D\) to \(\mathcal{C}/c_0\) (which satisfies \(U_{c_0} \circ D_\xi = D\)).

Then \(\xi\) is sent by the canonical functor \(l : \mathcal{C} \to \text{Sh}(\mathcal{C}, J)\) to a colimit cocone if and only if the functor \(D_\xi\) is \(J_{c_0}\)-cofinal, equivalently if and only if the following conditions are satisfied:

1. **(i)** For any object \(c\) of \(\mathcal{C}\) and any arrow \(y : c \to c_0\) in \(\mathcal{C}\) there are a \(J\)-covering family \(\{f_i : c_i \to c \mid i \in I\}\) and for each \(i \in I\) an object \(a_i\) of \(\mathcal{A}\) and an arrow \(y_i : c_i \to D(a_i)\) such that \(y \circ f_i = \xi_{a_i} \circ y_i\).

2. **(ii)** For any object \(c\) of \(\mathcal{C}\) and any arrows \(x : c \to D(a)\) and \(x' : c \to D(b)\) in \(\mathcal{C}\) such that \(\xi_a \circ x = \xi_b \circ x'\) there is a \(J\)-covering family \(\{f_i : c_i \to c \mid i \in I\}\) such that \(x \circ f_i\) and \(x' \circ f_i\) belong to the same connected component of the category \((c_i \downarrow D)\) for each \(i \in I\).
Characterization of colimits in toposes

This notion of relative cofinality has several applications. A basic one is the characterization of colimits in Grothendieck toposes in terms of generalized elements:

**Corollary**

Let $D : \mathcal{A} \to \mathcal{E}$ be a functor from a small category $\mathcal{A}$ to a Grothendieck topos $\mathcal{E}$ and $\xi$ a cocone

\[ \{ \xi_a : D(a) \to e_0 \mid a \in \mathcal{A} \} \]

under $D$ with vertex $e_0$. Then $\xi$ is a colimit cocone if and only if the functor $D_\xi$ is $(J_\mathcal{E}^{\text{can}})_{e_0}$-cofinal, equivalently if and only if the following conditions are satisfied:

(i) For any object $e$ of $\mathcal{E}$ and any arrow $y : e \to e_0$ in $\mathcal{E}$ there are an epimorphic family \( \{ f_i : e_i \to e \mid i \in I \} \) in $\mathcal{E}$ and for each $i \in I$ an object $a_i$ of $\mathcal{A}$ and an arrow $y_i : e_i \to D(a_i)$ such that $y \circ f_i = \xi_{a_i} \circ y_i$.

(ii) For any object $e$ of $\mathcal{E}$ and any arrows $x : e \to D(a)$ and $x' : e \to D(b)$ in $\mathcal{E}$ such that $\xi_a \circ x = \xi_b \circ x'$ there is an epimorphic family \( \{ f_i : e_i \to e \mid i \in I \} \) in $\mathcal{E}$ such that $x \circ f_i$ and $x' \circ f_i$ belong to the same connected component of the category $(e_i \downarrow D)$ for each $i \in I$.

Denseness conditions

Characterization of invariant properties of morphisms

Characterizations in terms of comorphisms of sites

Local morphisms

Characterization of continuous functors

Let

$$D^A_S : \int S \to \mathcal{D}$$

be the functor sending any \((d, f)\) of \(\int S\) to \(A(d)\), together with the cocone \(\xi_A\) with vertex \(A(c)\) under it (whose legs are the arrows \(A(f) : A(d) = D^A_S((d, f)) \to A(c)\) for any object \((d, f)\) of \(\int S\)).

Applying one of the above corollaries to it, we obtain the following explicit characterization of \((J, K)\)-continuous functors:

**Proposition**

Let \((\mathcal{C}, J)\) and \((\mathcal{D}, K)\) be small-generated sites. Then a functor \(A : \mathcal{C} \to \mathcal{D}\) is \((J, K)\)-continuous if and only if it is cover-preserving (i.e., sends \(J\)-covering families to \(K\)-covering ones) and for any \(J\)-covering sieve \(S\) on an object \(c\) and any commutative square of the form

\[
\begin{array}{ccc}
  d & \longrightarrow & A(c') \\
  \downarrow & & \downarrow_{A(f)} \\
  A(c'') & \longrightarrow & A(c),
\end{array}
\]

where \(f : c' \to c\) and \(g : c'' \to c\) are arbitrary arrows of \(S\), there is a \(K\)-covering family \(\{d_i \to d \mid i \in I\}\) such that for each \(i \in I\), the composites \(d_i \to A(c')\) and \(d_i \to A(c'')\) belong to the same connected component of the category \((d_i \downarrow D^A_S)\).

Indeed, the conditions of the proposition are equivalent to the requirement that that the lift

\[
(D^A_S)\xi_A : \int S \to \mathcal{D}/A(c)
\]

of the diagram \(D^A_S\) to \(\mathcal{D}/A(c)\) induced by the cocone \(\xi_A\) be \(K_{A(c)}\)-cofinal.
Continuity of (morphisms of) fibrations

By using the above characterization of continuous functors, one can prove

**Proposition**

Let \( A : \mathcal{C} \to \mathcal{D} \) be a fibration. Then, for any Grothendieck topology \( K \) on \( \mathcal{D} \), \( A \) is a continuous comorphism of sites \( (\mathcal{C}, M^A_K) \to (\mathcal{D}, K) \).

More generally, we have the following result:

**Theorem**

For any Grothendieck topology \( K \) on \( \mathcal{D} \), every morphism of fibrations \( (A : \mathcal{C} \to \mathcal{D}) \to (A' : \mathcal{C}' \to \mathcal{D}) \) is a continuous comorphism of sites \( (\mathcal{C}, M^A_K) \to (\mathcal{C}', M^{A'}_K) \).
Classifying essential morphisms

Recall that a geometric morphism $f : \mathcal{F} \to \mathcal{E}$ is said to be \textbf{essential} if its inverse image $f^*$ has a left adjoint, denoted by $f_!$ and called its \textit{essential image}.

**Theorem**

Let $(\mathcal{C}, J)$ be a small-generated site, $\mathcal{E}$ a Grothendieck topos. Let $\text{Geom}_{\text{ess}}(\text{Sh}(\mathcal{C}, J), \mathcal{E})$ be the category of essential geometric morphisms, and $\text{Com}_{\text{cont}}((\mathcal{C}, J), (\mathcal{E}, J_{\mathcal{E}}^{\text{can}}))$ the category of $J$-continuous comorphisms of sites $(\mathcal{C}, J) \to (\mathcal{E}, J_{\mathcal{E}}^{\text{can}})$. Then we have an equivalence

$$\text{Geom}_{\text{ess}}(\text{Sh}(\mathcal{C}, J), \mathcal{E}) \simeq \text{Com}_{\text{cont}}((\mathcal{C}, J), (\mathcal{E}, J_{\mathcal{E}}^{\text{can}}))$$

sending an essential geometric morphism $f = (f_! \dashv f^* \dashv f_* )$ to the comorphism of sites $f ! \circ l$ and a $J$-continuous comorphism of sites $A$ to the geometric morphism $C_A$ induced by it.

We say that two comorphisms of sites $A, A' : (\mathcal{C}, J) \to (\mathcal{D}, K)$ are $K$-equal\textit{enuivalent} if the geometric morphisms $C_A$ and $C_{A'}$ that they induce are isomorphic.

**Corollary**

Let $(\mathcal{C}, J)$ and $(\mathcal{D}, K)$ be small-generated sites. Then we have an equivalence between the essential geometric morphisms $f : \text{Sh}(\mathcal{C}, J) \to \text{Sh}(\mathcal{D}, K)$ such that $f_! \circ l : \mathcal{C} \to \text{Sh}(\mathcal{D}, K)$ factors through the canonical functor $l' : \mathcal{D} \to \text{Sh}(\mathcal{D}, K)$ and the $(J, K)$-continuous comorphism of sites $(\mathcal{C}, J) \to (\mathcal{D}, K)$, considered up to $K$-equivalence.
Continuous comorphisms of sites

The following result provides alternative characterizations for the property of a comorphism of sites to be continuous:

**Proposition**

Let $A : (C, J) \to (D, K)$ be a comorphism of sites. Then the following conditions are equivalent:

(i) $A$ is $(J, K)$-continuous.

(ii) The left Kan extension functor $\text{Lan}_{A^{op}} : [C^{op}, \text{Set}] \to [D^{op}, \text{Set}]$ along $A^{op}$ satisfies the property that $a_{K} \circ \text{Lan}_{A^{op}}$ factors (necessarily uniquely) through $a_{J}$.

(iii) The geometric morphism $C_{A}$ induced by $A$ is essential and its essential image $(C_{A})!$ makes the following diagram commute:

\[
\begin{array}{ccc}
[C^{op}, \text{Set}] & \xrightarrow{\text{Lan}_{A^{op}}} & [D^{op}, \text{Set}] \\
\downarrow a_{J} & & \downarrow a_{K} \\
\text{Sh}(C, J) & \xrightarrow{(C_{A})!} & \text{Sh}(D, K)
\end{array}
\]

If $A$ induces an essential geometric morphism $C_{A}$ then there is a canonical morphism $(C_{A})! \circ I \to l' \circ A$, and $A$ is $(J, K)$-continuous if and only if this morphism is an isomorphism, equivalently if and only if the canonical morphism

\[(C_{A})! \circ a_{J} \to a_{K} \circ \text{Lan}_{A^{op}}\]

is an isomorphism.
Local connectedness

The notion of **locally connected morphism** represents a natural strengthening of the notion of essential morphism. Recall that a geometric morphism \( f : \mathcal{F} \to \mathcal{E} \) is said to be locally connected if \( f^* \) has an \( \mathcal{E} \)-indexed left adjoint, equivalently for any arrow \( h : A \to B \) in \( \mathcal{E} \), the square

\[
\begin{array}{ccc}
\mathcal{F} / f^*(B) & \xrightarrow{(f/B)!} & \mathcal{E} / B \\
\downarrow (f^* (h))^* & & \downarrow h^* \\
\mathcal{F} / f^*(A) & \xrightarrow{(f/A)!} & \mathcal{E} / A
\end{array}
\]

commutes.

The continuity of (morphisms of) fibrations implies that such comorphisms always induce essential geometric morphisms. One might thus wonder if these morphisms always induce locally connected morphisms. Interestingly, this is **true for fibrations** but **not** in general for morphisms of fibrations.
Characterizing locally connected morphisms

In order to characterize locally connected morphisms, we need to introduce the following

**Definition**

Given a functor $F : \mathcal{C} \to \mathcal{D}$, an arrow $h : d_0 \to d_1$ in $\mathcal{D}$, an object $c$ of $\mathcal{C}$ and an arrow $x : F(c) \to d_1$ in $\mathcal{D}$:

(i) The category $\mathcal{A}^h_{(c,x)}$ has as objects the triplets $(c', y, f)$ where $c'$ is an object of $\mathcal{C}$, $y$ is an arrow $F(c') \to d_0$ in $\mathcal{D}$ and $f : c' \to c$ is an arrow of $\mathcal{C}$ such that $x \circ F(f) = h \circ y$, and as arrows $(c_1, y_1, f_1) \to (c_2, y_2, f_2)$ the arrows $t : c_1 \to c_2$ in $\mathcal{C}$ such that $f_2 \circ t = f_1$ and $y_2 \circ F(t) = y_1$.

(ii) The category $\mathcal{B}^h_{(c,x)}$ has as objects the triplets $(d, z, g)$ where $d$ is an object of $\mathcal{D}$, $z$ is an arrow $d \to d_0$ in $\mathcal{D}$ and $g : d \to F(c)$ is an arrow of $\mathcal{D}$ such that $x \circ g = h \circ z$, and as arrows $(d_1, z_1, g_1) \to (d_2, z_2, g_2)$ in $\mathcal{B}^h_{(c,x)}$ the arrows $s : d_1 \to d_2$ in $\mathcal{D}$ such that $g_2 \circ s = g_1$ and $z_2 \circ s = z_1$.

(iii) The categories $\mathcal{A}^h_{(c,x)}$ and $\mathcal{B}^h_{(c,x)}$ are actually fibered over $\mathcal{D}$. We shall denote by $a^h_{(c,x)} : \mathcal{A}^h_{(c,x)} \to \mathcal{D}$ the functor sending any object $(c', y, f)$ of $\mathcal{A}^h_{(c,x)}$ to the object $F(c')$ of $\mathcal{D}$ and any arrow $s : (c_1, y_1, f_1) \to (c_2, y_2, f_2)$ in $\mathcal{A}^h_{(c,x)}$ to the arrow $F(s) : F(c_1) \to F(c_2)$ of $\mathcal{D}$, and by $b^h_{(c,x)} : \mathcal{B}^h_{(c,x)} \to \mathcal{D}$ the canonical projection functor.

(iv) The functor $\xi^h_{(c,x)} : a^h_{(c,x)} \to b^h_{(c,x)}$ sends any object $(c', y, f)$ of $\mathcal{A}^h_{(c,x)}$ to the object $(F(c'), y, F(f))$ of $\mathcal{B}^h_{(c,x)}$ and any arrow $s : (c_1, y_1, f_1) \to (c_2, y_2, f_2)$ in $\mathcal{A}^h_{(c,x)}$ to the arrow $F(s) : (F(c_1), y_1, F(f_1)) \to (F(c_2), y_2, F(f_2))$ of $\mathcal{B}^h_{(c,x)}$. In fact, $\xi^h_{(c,x)}$ is a morphism of fibrations $a^h_{(c,x)} \to b^h_{(c,x)}$.

Corollary

Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor. Then the geometric morphism

\[
E(F) : [\mathcal{C}^{\text{op}}, \mathsf{Set}] \to [\mathcal{D}^{\text{op}}, \mathsf{Set}]
\]

induced by \( F \) is locally connected if and only if for any arrow \( h : a_0 \to a_1 \) in \( \mathcal{D} \), object \( c \) of \( \mathcal{C} \) and arrow \( x : F(c) \to d_1 \) in \( \mathcal{D} \), the following conditions hold:

(a) For any object \((d, z, g)\) of the category \( \mathcal{B}^h_{(c, x)} \) there is an object \((c', y, f)\) of the category \( \mathcal{A}^h_{(c, x)} \) and an arrow

\[
s : d \to F(c') = a^h_{(c, x)}((c', y, f))
\]

such that

\[
1_d : d \to d = b^h_{(c, x)}((d, z, g))
\]

and

\[
s : d \to F(c') = b^h_{(c, x)}((F(c'), y, F(f)))
\]

belong to the same connected component of the category \((d \downarrow b^h_{(c, x)})\).

(b) For any object \( d \) of \( \mathcal{D} \) and any arrows

\[
\alpha : d \to a^h_{(c, x)}((a, y, f)) = F(a) \text{ and } \\
\beta : d \to a^h_{(c, x)}((b, y', f')) = F(b) \text{ in } \mathcal{D} \text{ such that}
\]

\[
\alpha : d \to b^h_{(c, x)}((F(a), y, F(f))) = F(a)
\]

and

\[
\beta : d \to b^h_{(c, x)}((F(b), y', F(f'))) = F(b)
\]

belong to the same connected component of the category \((d \downarrow b^h_{(c, x)})\),

\[
\alpha : d \to a^h_{(c, x)}((a, y, f)) = F(a)
\]

and

\[
\beta : d \to b^h_{(c, x)}((b, y', f')) = F(b)
\]

belong to the same connected component of the category \((d \downarrow a^h_{(c, x)})\).

This extends a partial result obtained in this connection by Johnstone.
The terminally connected factorization

We shall say that an essential geometric morphism $f : \mathcal{F} \to \mathcal{E}$ is **terminally connected** if $f_!(1_{\mathcal{F}})$ is the terminal object of $\mathcal{E}$.

Recall that a local homeomorphism is a geometric morphism of the form $\mathcal{E}/A \to \mathcal{E}$ for an object $A$ of $\mathcal{E}$.

**Theorem**

(i) **Terminally connected morphisms are orthogonal to local homeomorphisms** in the 2-category of Grothendieck toposes; that is, for any commutative square

```
\begin{array}{ccc}
\mathcal{F} & \xrightarrow{f} & \mathcal{E} \\
\downarrow m & & \downarrow n \\
\mathcal{G} & \xleftarrow{g} & \mathcal{H}, \\
\end{array}
```

where $f$ is terminally connected and $g$ is a local homeomorphism, there exists a morphism $k : \mathcal{E} \to \mathcal{G}$ (unique up to unique 2-isomorphism) making both triangles commute.

(ii) **Any essential geometric morphism can be factored, uniquely up to equivalence, as a terminally connected morphism followed by a local homeomorphism.** More specifically, an essential geometric morphism $f : \mathcal{F} \to \mathcal{E}$ factors as a terminally connected morphism $f' : \mathcal{F} \to \mathcal{E}/f_!(1)$ followed by the canonical local homeomorphism $\mathcal{E}/f_!(1) \to \mathcal{E}$.

This factorization generalizes the well-known factorization of a locally connected morphism as a connected and locally connected morphism followed by a local homeomorphism.
The relative comprehensive factorization

By using our notion of relative cofinality, we can interpret the terminally connected factorization of an essential geometric morphism induced by a continuous comorphism of sites at the level of sites, as follows:

Given a functor $F : \mathcal{C} \to \mathcal{D}$ and a Grothendieck topology $K$ on $\mathcal{D}$, we associate with it the $K$-sheaf $F_K = \text{colim}_{\mathcal{D},K}(l' \circ F)$. We say that a discrete fibration to $\mathcal{D}$ is $K$-glueing if the presheaf corresponding to it is a $K$-sheaf.

Note that there is a canonical functor $\xi^F_K : \mathcal{C} \to \int F_K$ such that $\pi_{F_K} \circ \xi^F_K = F$, where $\pi_{F_K}$ is the canonical projection functor $\int F_K \to \mathcal{D}$.

**Definition**

Let $F : \mathcal{C} \to \mathcal{D}$ be a functor and $K$ a Grothendieck topology on $\mathcal{D}$. The $K$-comprehensive factorization of $F$ is given by the composite $F_K \circ \xi^F_K$:
The relative comprehensive factorization

**Theorem**

Let $F : \mathcal{C} \to \mathcal{D}$ be a functor and $K$ a Grothendieck topology on $\mathcal{D}$.

(i) The $K$-comprehensive factorization of $F$ is characterized by being the unique (up to equivalence) factorization of $F$ as a $M^p_K$-cofinal functor $\mathcal{C} \to \mathcal{E}$ followed by a $K$-glueing fibration $p : \mathcal{E} \to \mathcal{D}$.

(ii) If $F$ is a continuous comorphism of sites $(\mathcal{C}, J) \to (\mathcal{D}, K)$ then $\xi^F_K : (\mathcal{C}, J) \to (\int F_K, M^\pi_{\xi^F_K})$ and $F_K : (\int F_K, M^{\pi_{\xi^F_K}}) \to (\mathcal{D}, K)$ are continuous comorphism of sites and $C_F \cong C_{F_K} \circ C_{\xi^F_K}$ is the terminally connected-local homeomorphism factorization of the geometric morphism $C_F : \text{Sh}(\mathcal{C}, J) \to \text{Sh}(\mathcal{D}, K)$.

Equivalences of toposes

We shall present several results around the theme of equivalences of toposes.

In particular, we will present a characterization theorem providing necessary and sufficient explicit conditions for a morphism of sites to induce an equivalence of toposes. This generalizes the following classical result:

**Theorem (Grothendieck’s Comparison Lemma)**

Let $(\mathcal{C}, J)$ be a small-generated site and $\mathcal{D}$ be a $J$-dense subcategory of $\mathcal{C}$. Then the sieves in $\mathcal{D}$ of the form $R \cap \text{arr}(\mathcal{D})$ for a $J$-covering sieve $R$ in $\mathcal{C}$ form a Grothendieck topology $J|_\mathcal{D}$ on $\mathcal{D}$, and, denoting by $i : \mathcal{D} \to \mathcal{C}$ the canonical inclusion functor, the essential geometric morphism

$$E(i) : [\mathcal{D}^{\text{op}}, \text{Set}] \to [\mathcal{C}^{\text{op}}, \text{Set}],$$

induced by $i$ restricts to an equivalence of categories

$$\text{Sh}(\mathcal{D}, J|_\mathcal{D}) \simeq \text{Sh}(\mathcal{C}, J).$$

For this, we need to introduce general denseness conditions.
Denseness conditions

Definition
Let $F : \mathcal{C} \to \mathcal{D}$ be a functor and $J$ (resp. $K$) a Grothendieck topology on $\mathcal{C}$ (resp. on $\mathcal{D}$). Then $F$ is said to be
(a) $(J, K)$-faithful (resp. $J$-faithful) if whenever $F(h) \equiv_K F(k)$ (resp. $F(h) = F(k)$), $h \equiv_J k$;
(b) $(J, K)$-full (resp. $J$-full) if for every $x, y \in \mathcal{C}$ and any arrow $g : F(x) \to F(y)$ in $\mathcal{D}$, there exist a $J$-covering family of arrows $f_i : x_i \to x$ and arrows $g_i : x_i \to y$ (for each $i \in I$) such that $g \circ F(f_i) \equiv_K F(g_i)$ (resp. $g \circ F(f_i) = F(g_i)$) for all $i$;
(c) $K$-dense if for every $d \in \mathcal{D}$, there exists a $K$-covering family of arrows whose domains are in the image of $F$.

Recall that a functor $(\mathcal{C}, J) \to (\mathcal{D}, K)$ is said to be dense if it is $J$-faithful, $J$-full and $K$-dense, and it preserves and reflects covering families. Actually, the $J$-faithfulness condition is redundant for morphisms of sites since it follows from the latter condition by definition of a morphism of sites.

It was shown by Shulman (in his paper “Exact completions and small sheaves”) that every dense morphism of sites induces an equivalence of toposes. Still, as we shall see, being dense is not a necessary condition for a morphism of sites to induce an equivalence of toposes. For this one needs a more refined notion of denseness, which we shall call weak denseness.
Weakly dense morphisms

Recall that a Grothendieck topology on a locally small category is said to be subcanonical if all the representables are sheaves for it.

In order to characterize the morphisms of sites which induce an equivalence of toposes, we shall proceed in two steps:

(1) We will show that if \( F : (\mathcal{C}, J) \to (\mathcal{D}, K) \) is a morphism towards a subcanonical site \((\mathcal{D}, K)\) which induces an equivalence

\[
\text{Sh}(F) : \text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{C}, J)
\]

then \( F \) is dense.

(2) We will associate with \((\mathcal{D}, K)\) a Morita-equivalent subcanonical site, replace \( F \) with a morphism to this site inducing the same geometric morphism, and rephrase in terms of \( F \) the property of this latter morphism to be dense.
Weakly dense morphisms

Given a small-generated site \((C, J)\) and the canonical functor \(l : C \rightarrow \text{Sh}(C, J)\), we define \(a_J(C)\) to be the full (dense) subcategory of \(\text{Sh}(C, J)\) on the objects of the form \(l(c)\) for \(c \in C\). We denote by \(C_J^C\) the Grothendieck topology \(J_{\text{Sh}(C,J)}^{\text{can}}|_{a_J(C)}\) induced by the canonical Grothendieck topology on the topos \(\text{Sh}(C, J)\) on it.

- We have an equivalence

\[
\text{Sh}(D, K) \simeq \text{Sh}(a_K(D), C_K^D)
\]

induced by the morphism of sites

\[
l' : (D, K) \rightarrow (a_K(D), C_K^D).
\]

- The site \((a_K(D), C_K^D)\) is subcanonical and the morphism of sites

\[
l \circ F : (C, J) \rightarrow (a_K(D), C_K^D)
\]

induces the same geometric morphism (up to equivalence) as \(F\).

This motivates the following

**Definition**

We shall say that a morphism of sites \(F : (C, J) \rightarrow (D, K)\) is **weakly dense** if the morphism of sites \(l' \circ F : (C, J) \rightarrow (a_K(D), C_K^D)\) is dense.
Characterization of weakly dense morphisms

By using notably the explicit local description of arrows in a Grothendieck topos obtained above, one can prove the following

**Proposition**

Let $F : (\mathcal{C}, J) \to (\mathcal{D}, K)$ be a morphism of sites. Then $F$ is a weakly dense morphism of sites if and only if it satisfies the following conditions:

1. $P$ is a $J$-covering family in $\mathcal{C}$ if and only if $F(P)$ is a $K$-covering family in $\mathcal{D}$;
2. for any object $d$ of $\mathcal{D}$ there exist a family $\{S_i \mid i \in I\}$ of $K$-covering sieves on objects of the form $F(c_i)$ (where $c_i$ is an object of $\mathcal{C}$) and for each $f \in S_i$ an arrow $g_f : \text{dom}(f) \to d$ such that $g_{f \circ z} \equiv_K g_f \circ z$ whenever $z$ is composable with $f$, such that the family of arrows $g_f$ (for $f \in S_i$ for some $i$) is $K$-covering;
3. for any objects $x, y$ of $\mathcal{C}$ and any family of arrows $g_h : \text{dom}(h) \to F(y)$ indexed by the arrows of a $K$-covering sieve $U$ on $F(x)$ such that $g_{h \circ k} \equiv_K g_h \circ k$ for every arrow $k$ composable with $h$, there exist a $J$-covering family of arrows $\{f_i : x_i \to x \mid i \in I\}$ and arrows $k_i : x_i \to y$ (for each $i \in I$) such that for every arrows $w$ and $z$ such that $F(f_i) \circ w = h \circ z$, we have $g_h \circ z \equiv_K F(k_i) \circ w$ (for every $h \in U$ and $i \in I$).
The characterization theorem

Summarizing, we obtain the following general version of the Comparison Lemma:

**Theorem**

Let \( F : (\mathcal{C}, J) \to (\mathcal{D}, K) \) be a morphism of small-generated sites. Then the following conditions are equivalent:

(i) The geometric morphism \( \text{Sh}(F) : \text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{C}, J) \) is an equivalence.

(ii) \( l' \circ F : (\mathcal{C}, J) \to (a_K(\mathcal{D}), C^D_K) \) is a dense morphism of sites.

(iii) \( F \) is a weakly dense morphism of sites \( (\mathcal{C}, J) \to (\mathcal{D}, K) \) (i.e. it satisfies the conditions of the above proposition).

If \( K \) is subcanonical then any of the above conditions is equivalent to the requirement that \( F \) should be dense.

Applying this result to flat \( J \)-continuous functors \( F : \mathcal{C} \to \mathcal{E} \) (regarded as morphisms of sites \( (\mathcal{C}, J) \to (\mathcal{E}, J^\text{can}_\mathcal{E}) \)), we obtain the following criterion:

**Corollary**

Let \( (\mathcal{C}, J) \) be a small-generated site, \( \mathcal{E} \) a Grothendieck topos and \( F : \mathcal{C} \to \mathcal{E} \) a \( J \)-continuous flat functor. Then the geometric morphism \( f : \mathcal{E} \to \text{Sh}(\mathcal{C}, J) \) induced by \( F \) is an equivalence if and only if \( F \) satisfies the following conditions:

(i) If the image under \( F \) of a sieve \( S \) in \( \mathcal{C} \) is epimorphic in \( \mathcal{E} \) then \( S \) is \( J \)-covering;

(ii) the family of objects of the form \( F(c) \) for \( c \in \mathcal{C} \) is separating for \( \mathcal{E} \);

(iii) for every \( x, y \in \mathcal{C} \) and any arrow \( g : F(x) \to F(y) \) in \( \mathcal{E} \), there exist a \( J \)-covering family of arrows \( f_i : x_i \to x \) and a family of arrows \( g_i : x_i \to y \) such that \( g \circ F(f_i) = F(g_i) \) for all \( i \).
Denseness and weak denseness

We have seen that the notions of weak denseness and of denseness coincide if the codomain site is subcanonical.

The following countexample shows that, indeed, they do not coincide in general:

**Example**

Let $2$ be the preorder category with two distinct objects $0$ and $1$ and just one arrow $0 \to 1$ apart from the identities. Let us equip $2$ with the atomic topology $J_{at}$. The functor $F : 2 \to 2$ sending $0$ to $1$, $1$ to $1$ and the arrow $0 \to 1$ to the identity arrow on $1$ is a morphism of sites $(2, J_{at}) \to (2, J_{at})$ which induces an equivalence of toposes (note that $\text{Sh}(2, J_{at}) \simeq \text{Set}$ by the Comparison Lemma). Therefore, by our characterization theorem, $F$ is a weakly dense. However, $F$ is not a dense morphism of sites (since it is not $J_{at}$-dense).
Denseness and weak denseness

Given a morphism of sites $F: (C, J) \rightarrow (D, K)$, we have an induced functor $a_F : a_J(C) \rightarrow a_K(D)$ given by the restriction of the inverse image of the induced geometric morphism $\text{Sh}(F)$, which is a morphism of sites

$$a_F : (a_J(C), C_J) \rightarrow (a_K(D), C_K)$$

Recall that a functor between sites is said to satisfy the covering-lifting property if it is a comorphism between these sites. The following proposition further illuminates the relationship between denseness and weak denseness:

**Proposition**

Let $F: (C, J) \rightarrow (D, K)$ be a morphism of sites. Then

(i) $F$ is $(J, K)$-faithful if and only if $a_F$ is faithful;

(ii) Supposing that $F$ is $(J, K)$-faithful, if $a_F$ is full, $F$ is $(J, K)$-full, and the converse holds if $F$ satisfies the covering-lifting property;

(iii) If $F$ is $K$-dense then $a_F$ is $C_K^D$-dense, and the converse holds if $F$ satisfies the covering-lifting property.

Indeed, by using the proposition, one can show the following

**Corollary**

Let $F$ be a morphism of sites $(C, J) \rightarrow (D, K)$. Then the following conditions are equivalent:

(i) $F$ is a weakly dense and has the covering-lifting property;

(ii) $F$ is dense.
Morita equivalence of sites

Theorem
Let \((\mathcal{C}, J)\) and \((\mathcal{D}, K)\) be two small-generated sites. Then the following conditions are equivalent:

(i) \(\text{The toposes } \text{Sh}(\mathcal{C}, J)\) and \(\text{Sh}(\mathcal{D}, K)\) are equivalent.

(ii) \(\text{There exist a category (resp. an essentially small category, if } \mathcal{C} \text{ and } \mathcal{D} \text{ are essentially small) } \mathcal{A}, \text{ a Grothendieck topology } Z \text{ on } \mathcal{A} \) \(\text{(which can be supposed subcanonical)}\) and two functors \(H : \mathcal{C} \to \mathcal{A}\) and \(K : \mathcal{D} \to \mathcal{A}\) satisfying the following conditions:

   (i) \(P \text{ is a } J\)-covering family in } \mathcal{C} \text{ if and only if } H(P) \text{ is a } Z\)-covering family in } \mathcal{A};

   (ii) \(Q \text{ is a } K\)-covering family in } \mathcal{D} \text{ if and only if } K(Q) \text{ is a } Z\)-covering family in } \mathcal{A};

   (iii) \(\text{for any object } a \text{ of } \mathcal{A} \text{ there exists a } Z\text{-covering sieve whose arrows factor both through an arrow whose domain is in the image of } H \text{ and through an arrow whose domain is in the image of } K;\)

Morita equivalence of sites

Sketch of proof.

The conditions of the theorem are precisely those for the functor $H$ and $K$ to respectively define dense morphisms of sites $(\mathcal{C}, J) \to (\mathcal{A}, Z)$ and $(\mathcal{D}, K) \to (\mathcal{A}, Z)$.

On the other hand, if $\text{Sh}(\mathcal{C}, J) \simeq \text{Sh}(\mathcal{D}, K)$ then, by taking, for instance, $\mathcal{A}$ to be the full subcategory of this topos on the objects that are either coming from the site $(\mathcal{C}, J)$ or from the site $(\mathcal{D}, K)$ with the Grothendieck topology $Z$ induced on it by the canonical topology on the topos, we obtain by the Comparison Lemma equivalences $\text{Sh}(\mathcal{C}, J) \simeq \text{Sh}(\mathcal{A}, Z)$ and $\text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{A}, Z)$, whence by one of the above theorems the canonical functors $\mathcal{C} \to \mathcal{A}$ and $\mathcal{D} \to \mathcal{A}$ are respectively dense morphisms of sites $(\mathcal{C}, J) \to (\mathcal{A}, Z)$ and $(\mathcal{D}, K) \to (\mathcal{A}, Z)$. 

\[\square\]
Recall that a geometric morphism $f : \mathcal{F} \to \mathcal{E}$ is said to be

- a **surjection** if $f^*$ is faithful;
- an **inclusion** if $f_*$ is full and faithful.

Every geometric morphism can be factored, uniquely up to commuting equivalence, as the composite of a surjection followed by an inclusion. In fact, surjections and inclusions are orthogonal to each other. This implies that a geometric morphism is an equivalence if and only if it is both a surjection and an inclusion.

As we shall see, surjections and inclusions, as well as the surjection-inclusion factorization, can be naturally characterized in terms of sites.
Characterizations of surjections and inclusions

**Theorem**

Let $F : (\mathcal{C}, J) \to (\mathcal{D}, K)$ be a morphism of small-generated sites. Then:

(i) The geometric morphism $\text{Sh}(F) : \text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{C}, J)$ induced by $F$ is a *surjection* if and only if $F$ is *cover-reflecting* (that is, if the image of a family of arrows with a fixed codomain is $K$-covering then the family is $J$-covering).

(ii) The *surjection-inclusion factorization* of the geometric morphism $\text{Sh}(F) : \text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{C}, J)$ induced by $F$ can be identified with the factorization $\text{Sh}(i_{JF}) \circ \text{Sh}(F_r)$, where $J_F$ is the Grothendieck topology on $\mathcal{C}$ whose covering sieves are exactly those whose image under $F$ are $K$-covering families, $i_{JF} : (\mathcal{C}, J) \to (\mathcal{C}, J_F)$ is the morphism of sites given by the canonical inclusion functor and $F_r : (\mathcal{C}, J_F) \to (\mathcal{D}, K)$ is the morphism of sites given by $F$.

(iii) The geometric morphism $\text{Sh}(F) : \text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{C}, J)$ induced by $F$ is an *inclusion* if and only if $F_r : (\mathcal{C}, J_F) \to (\mathcal{D}, K)$ is a weakly dense morphism of sites; in particular, if $K$ is subcanonical then $\text{Sh}(F)$ is an inclusion if and only if the following conditions are satisfied:

(i) for any object $d$ of $\mathcal{D}$ there exists a $K$-covering family of arrows $d_i \to d$ whose domains $d_i$ are in the image of $F$;

(ii) for every $x, y \in \mathcal{C}$ and any arrow $g : F(x) \to F(y)$ in $\mathcal{D}$, there exist a $J_F$-covering family of arrows $f_i : x_i \to x$ and a family of arrows $g_i : x_i \to y$ such that $g \circ F(f_i) = F(g_i)$ for all $i$. 
Alternative characterization of inclusions

Corollary

Let $f : \mathcal{F} \to \mathcal{E}$ be a geometric morphism. Then $f$ is an inclusion if and only if $f^*$ satisfies the following conditions:

(i) $f^*$ is locally surjective, that is every object of $\mathcal{F}$ can be covered by objects in the image of $f^*$;

(ii) $f^*$ is locally full, that is for every $x, y \in \mathcal{E}$ and any arrow $g : f^*(x) \to f^*(y)$ in $\mathcal{F}$, there exists a family of arrows $s_i : x_i \to x$ in $\mathcal{E}$ which is sent by $f^*$ to an epimorphic family and a family of arrows $g_i : x_i \to y$ such that $g \circ f^*(s_i) = f^*(g_i)$ for all $i$.

Remark

Since a Grothendieck topos has all coproducts, the two above conditions for $f$ to be an inclusion are equivalent to the following ones:

(i) every object of $\mathcal{F}$ is a quotient of an object in the image of $f^*$;

(ii) for every $x, y \in \mathcal{E}$ and any arrow $g : f^*(x) \to f^*(y)$ in $\mathcal{F}$, there exist an arrow $s : x' \to x$ in $\mathcal{E}$ which is sent by $f^*$ to an epimorphism and an arrow $g' : x' \to y$ such that $g \circ f^*(s) = f^*(g')$. 
The induced topology

The following corollary of the above theorem shows that every morphism of sites naturally induces a Grothendieck topology on the domain category admitting a very simple description:

**Proposition**

Let \( f : \mathcal{E} \rightarrow [\mathcal{C}^{\text{op}}, \text{Set}] \) be a geometric morphism (equivalently, a flat functor \( F : \mathcal{C} \rightarrow \mathcal{E} \)). Then there exists a Grothendieck topology \( J_f \) (resp. \( J_F \)) on \( \mathcal{C} \), called the Grothendieck topology induced by \( f \) (resp. \( F \)) whose covering sieves are precisely the sieves which are sent by \( f^* \) (resp. by \( F \)) to epimorphic families in \( \mathcal{E} \). This applies in particular to a morphism of small-generated sites \( G : (\mathcal{C}, J) \rightarrow (\mathcal{D}, K) \), yielding a Grothendieck topology \( J_G \) on \( \mathcal{C} \) whose covering sieves are exactly those whose image under \( G \) are \( K \)-covering families.

In fact, \( J_G \) is the largest topology on \( \mathcal{C} \) which makes \( F \) continuous as a functor from \( \mathcal{C} \) to the site \( (\mathcal{D}, K) \).

As shown by the following result, the notion of induced topology can be profitably applied for establishing equivalences of toposes:

**Corollary**

Let \( \mathcal{C} \) be an essentially small category, \( \mathcal{E} \) a Grothendieck topos and \( F : \mathcal{C} \rightarrow \mathcal{E} \) a flat functor. Then \( F \) induces an equivalence

\[
\mathcal{E} \simeq \text{Sh}(\mathcal{C}, J_F),
\]

if and only if \( F \) is \( J_F \)-full and the objects of the form \( F(c) \) for \( c \in \mathcal{C} \) form a separating set for the topos \( \mathcal{E} \).
Hyperconnected and localic morphisms

Recall that a geometric morphism $f : \mathcal{F} \to \mathcal{E}$ is said to be

- **hyperconnected** if $f^*$ is full and faithful and its image is closed under subobjects in $\mathcal{F}$;
- **localic** if every object of $\mathcal{F}$ is a subquotient (that is, a quotient of a subobject) of an object of the form $f^*(A)$ for $A \in \mathcal{E}$.

Recall that every geometric morphism can be factored, uniquely up to commuting equivalence, as the composite of a hyperconnected morphism followed by a localic one. In fact, hyperconnected and localic morphisms are orthogonal to each other.
Characterizations for localic morphisms

Proposition

Let \((C, J)\) be a small-generated site, \(\mathcal{E}\) a Grothendieck topos and \(F : C \to \mathcal{E}\) a \(J\)-continuous flat functor inducing a geometric morphism \(f : \mathcal{E} \to \mathbf{Sh}(C, J)\). Then \(f\) is localic if and only if the subobjects of objects of the form \(F(c)\) for \(c \in C\) form a separating set for the topos \(\mathcal{E}\).

Proposition

Let \(F : (C, J) \to (D, K)\) be a morphism of small-generated sites. Then the geometric morphism \(\mathbf{Sh}(F) : \mathbf{Sh}(D, K) \to \mathbf{Sh}(C, J)\) induced by \(F\) is localic if and only if for any object \(d\) of \(D\) there exist a family \(\{S_i \mid i \in I\}\) of sieves on objects of the form \(F(c_i)\) (where \(c_i\) is an object of \(C\)) and for each \(f \in S_i\) an arrow \(g_f : \text{dom}(f) \to d\) such that \(g_{f \circ z} \equiv_K g_f \circ z\) whenever \(z\) is composable with \(f\), such that the family of arrows \(g_f\) (for \(f \in S_i\) for some \(i\)) is \(K\)-covering.
Characterizations for hyperconnected morphisms

Proposition

Let \((\mathcal{C}, J)\) be a small-generated site, \(\mathcal{E}\) a Grothendieck topos and \(F : \mathcal{C} \to \mathcal{E}\) a \(J\)-continuous flat functor. Then the geometric morphism \(f : \mathcal{E} \to \mathbf{Sh}(\mathcal{C}, J)\) induced by \(F\) is hyperconnected if and only if \(F\) is cover-reflecting and for every subobject \(A \hookrightarrow F(c)\) in \(\mathcal{E}\) there exists a (\(J\)-closed) sieve \(R\) on \(c\) such that \(A\) is the union of the images of the arrows \(F(f)\) for \(f \in R\).

Proposition

Let \(F : (\mathcal{C}, J) \to (\mathcal{D}, K)\) be a morphism of small-generated sites. Then the geometric morphism \(\mathbf{Sh}(F) : \mathbf{Sh}(\mathcal{D}, K) \to \mathbf{Sh}(\mathcal{C}, J)\) induced by \(F\) is hyperconnected if and only if \(F\) is cover-reflecting and closed-sieve-lifting, in the sense that for every object \(c\) of \(\mathcal{C}\) and any \(K\)-closed sieve \(S\) on \(F(c)\) there exists a (\(J\)-closed) sieve \(R\) on \(c\) such that \(S\) coincides with the \(K\)-closure of the sieve on \(F(c)\) generated by the arrows \(F(f)\) for \(f \in R\).

We have also obtained a site-theoretic description of the hyperconnected-localic factorization of the geometric morphism induced by a morphism of sites. This description specializes to a particularly elegant one in the case of the geometric morphism between the classifying toposes of two geometric theories induced by an interpretation of one theory into the other.
Corollary

Let \((\mathcal{C}, J)\) be a small-generated site, \(\mathcal{E}\) a Grothendieck topos and \(F : \mathcal{C} \to \mathcal{E}\) a \(J\)-continuous flat functor inducing a geometric morphism \(f : \mathcal{E} \to \text{Sh}(\mathcal{C}, J)\). Then \(f\) is an equivalence if and only if the following conditions are satisfied:

1. \(F\) is cover-reflecting;
2. for every subobject \(A \hookrightarrow F(c)\) in \(\mathcal{E}\) there exists a (\(J\)-closed) sieve \(R\) on \(c\) such that \(A\) is the union of the images of the arrows \(F(f)\) for \(f \in R\);
3. the objects of the form \(F(c)\) for \(c \in \mathcal{C}\) form a separating set for the topos \(\mathcal{E}\).

Corollary

Let \(f : \mathcal{F} \to \mathcal{E}\) be a geometric morphism. Then

1. \(f\) is an inclusion if and only if \(f^*\) is locally surjective and its image is closed under subobjects.
2. \(f\) is an equivalence if and only if \(f^*\) is faithful, locally surjective and its image is closed under subobjects.

By applying this latter corollary, we have obtained explicit and elegant characterizations of

- the interpretations of one geometric theory into another which identify the latter as a quotient of the former (up to Morita equivalence);
- the interpretations of one geometric theory into another which induce a Morita equivalence between them.
Characterizations in terms of comorphisms

We have obtained characterizations for the property of a comorphism of sites to induce a surjection (resp. an inclusion), as well as of the surjection-inclusion factorization of the associated geometric morphism. We have also derived characterizations for the property of a comorphism of sites to induce a hyperconnected (resp. a localic) morphism, as well as of the hyperconnected-localic factorization. Under the most general assumptions, these characterizations are normally rather technically involved.

Here are some of the simplest examples of such characterizations:

**Proposition**

*The geometric morphism* $C_F : \text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{C}, J)$ *induced by a comorphism of sites* $F : (\mathcal{D}, K) \to (\mathcal{C}, J)$ *is a surjection if and only if whenever a sieve* $S$ *on an object* $c \in \mathcal{C}$ *satisfies the property that for every object* $d$ *of* $\mathcal{D}$ *and arrow* $x : F(d) \to c$ *in* $\mathcal{C}$, *there exists a* $K$-*covering sieve* $T$ *on* $d$ *such that* $F(T) \subseteq x^*(S)$, *then* $S$ *is* $J$-*covering. This condition implies that* $F$ *is* $J$-*dense and is equivalent to it if* $F$ *is cover-preserving.*

**Proposition**

*Let* $F : (\mathcal{D}, K) \to (\mathcal{C}, J)$ *be a comorphism of sites which is cover-preserving. Then the surjection-inclusion factorization of the geometric morphism* $C_F : \text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{C}, J)$ *induced by* $F$ *can be identified with* $C_i \circ C_{F'}$, *where* $F'$ *is the functor* $F$ *regarded as a comorphism of sites from* $(\mathcal{D}, K)$ *to the site* $(\mathcal{C}', J')$, *where* $\mathcal{C}'$ *is the full subcategory of* $\mathcal{C}$ *on the objects in the image of* $F$ *and* $J'$ *is the smallest Grothendieck topology on* $\mathcal{C}'$ *making the inclusion* $i$ *of* $\mathcal{C}'$ *into* $\mathcal{C}$ *a comorphism of sites to* $(\mathcal{C}, J)$. 
Characterizations in terms of comorphisms

**Proposition**

Let $F : \mathcal{D} \to \mathcal{C}$ be a functor between essentially small categories. Then the geometric morphism $C_F : [\mathcal{D}^{\text{op}}, \text{Set}] \to [\mathcal{C}^{\text{op}}, \text{Set}]$ is hyperconnected if and only if $F$ is full and every object of $\mathcal{D}$ is a retract of an object in the image of $F$.

**Proposition**

Let $F : (\mathcal{D}, K) \to (\mathcal{C}, J)$ be a comorphism of sites which is cover-preserving. Then the hyperconnected-localic factorization of the geometric morphism $C_F : \text{Sh}(\mathcal{D}, K) \to \text{Sh}(\mathcal{C}, J)$ induced by $F$ can be identified with $C_{\tilde{F}} \circ C_\pi$, where $F$ is the functor $\tilde{F}$ regarded as a comorphism of sites from the site $(\mathcal{E}, L)$ whose underlying category $\mathcal{E}$ is the quotient of the category $\mathcal{D}$ by the congruence induced by $F$ and whose Grothendieck topology $L$ has as covering sieves the sieves whose inverse image under the canonical projection functor $\pi : \mathcal{D} \to \mathcal{E}$ is $K$-covering.
Local morphisms

Recall that a (weak) geometric morphism $f : \mathcal{F} \to \mathcal{E}$ is said to be local if $f_*$ has a fully faithful right adjoint.

**Theorem**

Let $F : \mathcal{D} \to \mathcal{C}$ be a continuous comorphism of sites (also regarded as a weak morphism of sites) $(\mathcal{D}, \mathcal{K}) \to (\mathcal{C}, \mathcal{J})$. Then:

(i) The geometric morphism $C_F : \text{Sh}(\mathcal{D}, \mathcal{K}) \to \text{Sh}(\mathcal{C}, \mathcal{J})$ is essential, and

$$
(C_F)_! \cong \text{Sh}(F)^* \dashv \text{Sh}(F)_* \cong (C_F)^* = D_F := (- \circ F^{\text{op}}) \dashv (C_F)_*
$$

(ii) If $F$ is a morphism of sites then the geometric morphisms $\text{Sh}(F)$ and $C_F$ form an adjoint pair in the 2-category $\mathcal{S}^\text{op}$ of Grothendieck toposes, geometric morphisms and geometric transformations.

(iii) The weak morphism $\text{Sh}(F) : \text{Sh}(\mathcal{C}, \mathcal{J}) \to \text{Sh}(\mathcal{D}, \mathcal{K})$ is local if and only if $C_F$ is an inclusion, that is, if and only if $F$ is $\mathcal{K}$-faithful and $\mathcal{K}$-full.

(iv) The canonical geometric transformation

$$1_{\text{Sh}(\mathcal{D}, \mathcal{K})} \to \text{Sh}(F) \circ C_F$$

(given by the unit of the adjunction between $\text{Sh}(F)$ and $C_F$) is an isomorphism if (and only if) $F$ is $\mathcal{K}$-faithful and $\mathcal{K}$-full. In this case, if $F$ is moreover a morphism of sites $(\mathcal{D}, \mathcal{K}) \to (\mathcal{C}, \mathcal{J})$, the morphisms $C_F$ and $\text{Sh}(F)$ realize the topos $\text{Sh}(\mathcal{D}, \mathcal{K})$ as a (coadjoint) retract of $\text{Sh}(\mathcal{C}, \mathcal{J})$ in $\mathcal{S}^\text{op}$.
Gros and petit toposes

The above result can be notably applied to construct pairs of *gros* and *petit toposes* starting from a \((K-)\)full and \((K-)\)faithful morphism and comorphism of sites

\[(\mathcal{D}, K) \to (\mathcal{T} / \mathcal{T}_D, E_{\mathcal{T}_D}),\]

where \(\mathcal{T}\) is a category endowed with a Grothendieck topology \(E\), \(\mathcal{T}_D\) is an object of \(\mathcal{T}\) and \(E_{\mathcal{T}_D}\) is the Grothendieck topology induced on \((\mathcal{T} / \mathcal{T}_D)\) by \(E\).

As an example, consider, for any small-generated site \((\mathcal{C}, J)\), the functor \(L : \mathcal{C} \to \mathcal{S}_{\mathcal{O}p} / \mathcal{S}_{\mathcal{H}}(\mathcal{C}, J)\) sending an object \(c\) of \(\mathcal{C}\) to the local homeomorphism \(\mathcal{S}_{\mathcal{H}}(\mathcal{C}, J) / l(c) \to \mathcal{S}_{\mathcal{H}}(\mathcal{C}, J)\). By equipping \(\mathcal{S}_{\mathcal{O}p}\) with the topology \(E\) generated by the families of local homeomorphisms \(\{E / A_i \to E \mid i \in I\}\) such that the family \(\{A_i \to 1_E\}\) is epimorphic, \(L\) becomes a \(J\)-full and \(J\)-faithful morphism and comorphism of sites \((\mathcal{C}, J) \to (\mathcal{S}_{\mathcal{O}p} / \mathcal{S}_{\mathcal{H}}(\mathcal{C}, J), E_{\mathcal{S}_{\mathcal{H}}(\mathcal{C}, J)})\) (where \(E_{\mathcal{S}_{\mathcal{H}}(\mathcal{C}, J)}\) is the Grothendieck topology whose covering sieves are those sent by the canonical projection \(\mathcal{S}_{\mathcal{O}p} / \mathcal{S}_{\mathcal{H}}(\mathcal{C}, J) \to \mathcal{S}_{\mathcal{O}p}\) to \(E\)-covering families), thus realizing \(\mathcal{S}_{\mathcal{H}}(\mathcal{C}, J)\) as a coadjoint retract of the gro\(s topos \(\mathcal{S}_{\mathcal{H}}(\mathcal{S}_{\mathcal{O}p}, E) / l(\mathcal{S}_{\mathcal{H}}(\mathcal{C}, J))\) (with respect to suitable Grothendieck universe), where \(l\) is the canonical functor \(\mathcal{S}_{\mathcal{O}p} \to \mathcal{S}_{\mathcal{H}}(\mathcal{S}_{\mathcal{O}p}, E)\).

This is part of a joint work-in-progress with my Ph.D. student Riccardo Zanfa, which constructs a whole framework for studying (relative) Grothendieck toposes from a geometric point of view, thus providing a solution to the questions posed by Grothendieck in his lecture course at Buffalo of 1973 and recently brought to the public attention by Colin McLarty.
